                                                                                                                                                                                                                                                                                                                                                                                                                         The present invention describes nucleic acid molecules which modulate the synthesis, expression and/or stability of a mRNA encoding 1 or more receptors of vascular endothelial growth factor (VEGF). A patient (preferably human) having a condition associated with the level of the fms-like tyrosine kinase 1 (flt-1), kinase insert domain containing anglogenesis, ocular diseases, psoriasis and rheumatoid arthritis) can be treated by administering the nucleic acid molecule or the expression vector to the patient. AAX67275 to AAX7572 represent specific examples of nucleic acid molecules from the present invention.
                                                                                   Vascular endothelial growth factor receptor; VEGF receptor; flt-1; flk-1; KDR; hammerhead ribozyme; hairpin ribozyme; cleavage; tumcur angiogenesis; psoriasis; rheumatoid archritis; ocular disease; fms-like tyrosine kinase 1; kinase insert domain containing receptor; foetal liver kinase 1; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Maize; corn; Zea mays; delta-9 desaturase; GBSS; target; substrate; granule bound starch synthase; hammerhead ribozyme; hairpin ribozyme; modulation; gene expression; transgenic plant; cleavage; canola plant;

The present invention describes an enzymatic nucleic acid molecule (I) with RNA cleaving activity, which modulates the expression of a plant gene. Also described is a gene comprising a cDNA sequence encoding maize Delta-9 desaturase. (I) can be used to modulate expression of a gene, preferably Delta-9 desaturase or a granule bound starch synthase (GBSS) gene, in a plant (preferably a maize or canola plant). (I) can be used to modulate caffeine synthesis in a coffee plant, nicotine production in plum or peach plant, flower pigmentation in a rose, petunia, chrysanthemum or marigold plant or lignin production in a tobacco, aspen, poplar or plant.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Maize; corn, Zea mays; delta-9 desaturase; GBSS; target; substrate; granule bound starch synthase; hammerhead ribozyme; hairpin ribozyme; modulation; gene expression; transgentc plant; oleavage; canola plant; caffeine synthesis; coffee plant; nicotine production; tobacco; fruit ripening; flower pigmentation; lignin production; se
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                starch
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Granule bound starch synthase hammerhead substrate SEQ ID NO:149.

The present invention describes enzymatic nucleic acid molecules (NAMs) which specifically cleave RNA derived from an epidermal growth factor receptor (EGF-R) gene. AAV97221 to AAV98043 and AAV98999 to AAV98090 represent specifically claimed target sequence from human EGF-R. AAV98044 to AAV98866 and AAV98867 to V9878 represent hammerhead ribozymes and
                                                                                                               This DNA fragment is part of the TURF 2H3 region of Zea Mays. TURF 2H3 (3547 nucleotides long) is found in mitochondrial DNA, and is uniquely arranged in maize affected by cytoplasm male sterility type T (cms-T). The present sequence corresponds to positions 1400-1416 of TURP 2H3, and is located in the middle of open reading frame 13. A synthetic has also been claimed. Both oligonucleotides can be useful sequence has also been claimed. Both oligonucleotides can be useful stopes to identify a restriction fragment whose size in cms-T mitochondrial DNA is different from the corresponding fragment in normal mitochondrial DNA is minimal mitochondrial DNA. They are useful for rapidly and specifically testing maize plants for
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Human, epidermal growth factor receptor; EGFR; EGF-R; target sequence;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   ö
                                                                                                                                                                                                                                                                                                                           The present invention describes an enzymatic nucleic acid molecule (1) with RNA cleaving activity, which modulates the expression of a plant defene. As described is a gene comprising a cDNA sequence encoding maize Delta-9 desaturase. (1) can be used to modulate expression of a gene, preferably Delta-9 desaturase or a granule bound starch synthase (GBSS) gene, in a plant (preferably a maize or canola plant). (1) can be used to modulate caffeine synthesis in a coffee plant, nicotine production in plum or peach plant, fruit ripening processes in an apple, tomato, pear, chrysanthemum or marigold plant or lignin production in a tobacco, appen, poplar or plant.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             DNA probe 1 specific for type-T cytoplasmic male sterility in Zea mays.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       TURF 2H3; maize, cytoplasm male sterility, cms, type T; cms-T; open reading frame 13; probe; restriction fragment; mitochondrial DNA;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Gaps

hairpin ribozymes respectively for human EGF-R. The NAMS are useful for cleaving EGF-R RNA in the treatment of a condition associated with EGFR expression levels e.g. to inhibit cell proliferation in the prevention or treatment of cancers. The NAMS can also be used as diagnostic tools to examine genetic drift and mutations within diseased cells or to detect the presence of EGF-R RNA in a cell.

New enzymatic nucleic acid(s) - useful for, e.g. reducing alkaloid blosynthesis or regulating flowering

Claim 53; Page 57; 79pp; English.

The present invention describes enzymatic nucleic acid molecules with RNA-cleaving activity (e.g. ribozymes) which are capable of modulating the expression of plant genes: (i) involved in biosynthesis of alkaloids; or (ii) involved in flower formation. AAV95982 to AAV96334, and AAV96355 to AAV96354 represent potato solanidine glucosyltransferase and AAV96355 to AAV96734 represent potato solanidine glucosyltransferase target sequences. AAV9673 to AAV97710, and AAV97171 to AAV97195 to AAV9673 to AAV96773 to AAV97710, and AAV97171 to AAV97195 co represent potato citrate synthase harmerhead and hairpin ribozymes, correspectively. AAV96735 to AAV96772, and AAV97196 to AAV97220 represent potato citrate synthase harmerhead and hairpin ribozymes. Correspectively. AAV96735 to AAV96772, and AAV97196 to AAV97720 represent potato citrate synthase target sequences. Ribozymes of the present cinvention can be used to inhibit flowering of toxic alkaloids in subergine and ditura or to inhibit flowering in potato, pepper, cabbage, brussel sprouts, arugula, kale, collarde, chard, beet, turnip, sweet potato and turk grass. Also the ribozymes can be used for RNA manipulation in the same way that restriction endonucleases are for DNA, as well as to examine genetic drift and mutations in plants and to

genes or detect specific RNA. The ribozymes can be targeted to specific gene to consensus sequences within a family of related genes, and being catalytic need to be present at only very low concentrations. \$\$\$\$\$\$

Novel ribozymes for modulating the synthesis, expression and/or stability of an mRNA encoding an angiogenic factors

Claim 56; Page 133; 305pp; English.

The present invention describes enzymatic nucleic acid molecules with CE RNA cleaving activity, which specifically cleave RNA encoded by an aryl bydrocarbon nuclear transporter (ARNY) gene, an integrin subunit beta 3 gene, an integrin alpha 6 subunit gene, or a Tie-2 gene. AAA11675 to AAA17167 to AAA17622 represent ribozyme sequences for ARNY, CC and AAA17168 to AAA17623 to AAA18385 and AAA18386 to AAA19087 to CAAA19154 represent ribozyme sequences; AAA19155 to AAA19152 represent their corresponding target sequences; CC AAA19154 represent ribozyme sequences for Tie-2, and AAA19186 to AAA19186 co AAA19185 represent ribozyme corresponding target sequences; AAA19153 to AAA19155 to AAA19155 to AAA19155 and AAA21501 to AAA2155 represent ribozyme sequences; CC AAA21956 to AAA21688 represent their corresponding target sequences; CC AAA21956 to AAA2168 and AAA22353 to AAA23342 represent ribozyme sequences cfor integrin subunit beta 3, and AAA23342 represent ribozyme sequence for integrin subunit beta 3, and AAA23475 to AAA23333 to AAA23422 represent their corresponding target sequences cfor integrin subunit beta 3, and AAA23475 represent ribozyme sequence corresponding target sequences. The ribozymes of the invention are used for modulating the synthesis, expression and/or stability of an mRNA encoding angiogenic factor, especially ARNT,

integrin subunit beta-3, integrin subunit alpha-6, or Tie-2. They are especially used to treat cancer, diabetic retinopathy, age related macular degeneration (ARMD), inflammation, and arthritis, as well as neovascular glaucoma, myopic degeneration, psoriasis, veruca vulgaris, angiofibroma of tuberous sclerosis, pot-wine stains, Sturge Weber syndrome, Kippel-Trenaunay-Weber syndrome, osler-Rendu syndrome, and other syndromes and other syndrome, and other syndromes and other syndromes. integrin subunit alpha-6, or integrin subunit beta-3. 8888888888888

Novel ribozymes for modulating the synthesis, expression and/or stability of an mRNA encoding an angiogenic factors

Claim 55; Page 188; 305pp; English.

The present invention describes enzymatic nucleic acid molecules with RNA cleaving activity, which specifically cleave RNA encoded by an aryl hydrocarbon nuclear transporter (ARNT) gene, an integrin subunit beta 3 gene, an integrin alpha 6 subunit gene, or a Tie-2 gene AAA16775 to AAA1767 and AAA17561 to AAA17622 represent ribozyme sequences for ARNT, and AAA17168 to AAA17560 and AAA17682 to AAA18895 and AAA19087 to Corresponding target sequences, AAA17685 to AAA19154 represent their corresponding target sequences for Tie-2, and AAA19187 to AAA19155 to AAA1922 represent their corresponding target sequences, AAA19223 to AAA1925 represent their corresponding target sequences, sequences for integrin alpha 6 subunit, and AAA20362 to AAA21500 and AAA21596 to AAA21688 represent their corresponding target sequences;

AAA21689 to AAA22475 and AAA23263 to AAA23342 represent ribozyme sequence for integrin subunit beta 3, and AAA22476 to AAA23262, AAA23343 to AAA23415 represent their corresponding target sequences. The ribozymes of the invention are used for modulating the synthesis, expression and/or stability of an mRNA encoding angiogenic factor, especially ARNT, integrin subunit beta-3, integrin subunit alpha-6, or Tie-2. They are especially used to treat cancer, diabetic retinopathy, age related macular degeneration (ARMD), inflammation, and arthritis, as well as neovascular glaucoma, myopic degeneration, psoriasis, verruca vulgaris, syndrome of tuberous sclerosis, pot-wine stains, Sturge Weber syndrome, ABADA-Rendu syndrome, and other syndrome. integrin subunit alpha-6, or integrin subunit beta-3

Novel ribozymes for modulating the synthesis, expression and/or stability of an mRNA encoding an angiogenic factors $\bar{\ }$

Claim 54; Page 231; 305pp; English.

The present invention describes enzymatic nucleic acid molecules with RNA cleaving activity, which specifically cleave RNA encoded by an aryl hydrocarbon nuclear transporter (ARNT) gene, an integrin subunit beta 3 gene, an integrin alpha 6 subunit gene, or a Tie-2 gene. AAA16775 to AAA17167 and AAA17761 to AAA17622 represent ribozyme sequences for ARNT, and AAA17560 and AAA17623 to AAA17684 represent their corresponding target sequences; AAA17685 to AAA18385 and AAA19087 to

and AAA19154 represent ribozyme sequences for Tie-2, and AAA18386 to AAA19086
and AAAA19155 to AAA19222 represent their corresponding target sequences;
AAA19223 to AAA20361 and AAA21501 to AAA11959 represent ribozyme
sequences for integrin alpha 6 sububit, and AAA20362 to AAA21500 and
AAA21689 to AAA21688 represent their corresponding target sequences;
AAA21689 to AAA22475 and AAA23263 to AAA23362, AAA2342 represent ribozyme sequence
for integrin subunit beta 3, and AAA23476 to AAA23422, AAA23433 and
AAA23422 represent their corresponding target sequences. The ribozymes of
the invention are used for modilating the synthesis, expression and/or
stability of an mRNA encoding angiogenic factor, especially ARNT,
creating subunit beta-3, integrin subunit alpha-6, or Tie-2. They are
sepecially used to treat cancer, diabetic retinopathy, age related
macular degeneration (ARMD), inflammation, and arthritis, as well as
neovascular glaucoma, myopic degeneration, psoriasis, verruca vulgaris,
angiofibroma of tuberous sclerosis, pot-wine stains, Sturge Weber
syndrome, Kippel-Trenaunay-Weber syndrome, osler-Weber-Rendu syndrome,
and other syndromes and diseases related to the levels of ARNT, Tie-2,
integrin subunit alpha-6, or integrin subunit beta-3.

Identifying new catalytic nucleic acid that modulates selected processes - especially ribozymes that cleave Raf RNA for treating cancer, restenosis, and also new ribozymes and modified nucleoside triphosphates used as antiviral agents and synthons

Claim 177; Page 160; 259pp; English.

capable of modulating a process in a biological system. The method comprises: (a) introducing into the system a random library of nucleic acid catalysets (NAC) having a substrate binding domain (SBD), comprising a random sequence, and a catalytic domain (CD); and (b) identifying NAC in systems where modulation has occurred and/or determining the sequence of at least part of the SBDs in such systems. Nucleic acid molecules with endonuclease activity and catalytic activity, from the present invention, are used to modulate gene expression in plant and mammalian cells and to cleave target nucleic acid, particularly for treating systemic diseases caused by specific RNA, e.g. cancer, inflammation, psortamis, non-hepatic ascites and infection. They may also be used to detect genetic drift and mutations in diseased cells and to determine craft RNA. Specifically NACs with RNA-cleaving activity that modulate expression of the Raf gene, are used to treat cancer, restenosis, psoriasis or rheumatoid arthritis, or generally any condition associated with the level of craft Introduction of sugar/phosphate modifications in chreases stability against nuclease and activity. AAV90922 to AAV93877 represent NACs that can be used in the method, specifically for modulating the expression of a Raf gene. A method has been developed for the identification of a nucleic acid

```
The present invention relates to enzymatic and antisense nucleic acid molecules that act as inhibitors of the expression of repressor genes encoding the TR2 Orphan receptor. EAR3/COUP-TR-1, the GATA transcription factor gene, TRF-2 and/or the CAATT Displacement Protein (CDP). Inhibition of the repressors removes prevents inhibition (and consequently increases expression of) genes involved in the production of erythropoietin, granulocyte colony stimulating factor protein and interferon alpha.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Enzymatic and antisense nucleic acid inhibition of repressor genes, useful for producing e.g. granulocyte colony stimulating factor protein, interferon alpha and erythropoietin -
                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Ribozyme; erythropoietin; granulocyte colony stimulating factor;

                                                                                                                                                                                                                                                                                                                                                                            The present invention relates to enzymatic and antisense nucleic acid molecules that act as inhibitors of the expression of repressor genes encoding the TR2 Orphan receptor. BAR3/COUD-TF-1, the GATA transcription factor gene, IRF-2 and/or the CAATT Displacement Protein (CDP). Inhibition of the repressors removes prevents inhibition (and consequently increases expression of) genes involved in the production of erythropoletin, granulocyte colony stimulating factor protein and interferon alpha.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps

The present invention relates to enzymatic and antisense nucleic acid molecules that act as inhibitors of the expression of repressor genes encoding the TR2 orphan receptor, EAR3/COUP-TF-1, the GATA transcription factor gene, IFF-2 and/or the CAMTH Displacement Protein (CDP). Inhibition of the repressors removes prevents inhibition (and consequently increases expression of) genes involved in the production of erychropoletin, gramulocyte colony stimulating factor protein and interferon alpha.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The present invention relates to enzymatic and antisense nucleic acid molecules that act as inhibitors of the expression of repressor genes encoding the TR2 Orphan receptor. BAR3/COUP-TF-1, the GATA transcription factor gene, TRR-2 and/or the CAATT Displacement Protein (CDP). Inhibition of the repressors removes prevents inhibition (and consequently increases expression of) genes involved in the production of erythropoietin, granulocyte colony stimulating factor protein and interferon alpha.
                                                                                                                                                                                                                                                                                                                                                                                 Gaps
                                                            Enzymatic and antisense nucleic acid inhibition of repressor genes, useful for producing e.g. granulocyte colony stimulating factor protein, interferon alpha and erythropoietin -
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Enzymatic and antisense nucleic acid inhibition of repressor genes, useful for producing e.g. granulocyte colony stimulating factor protein, interferon alpha and erythropoietin -

The method comprises preparing a reduced complexity genome (RCG) from the genomic sample and analysing the RCG for the presence or absence of a SNP allele. The method can be used to characterise a tumour, to generate a genomic pattern for an individual genome or to generate a genomic classification code for a genome. The method can be used to assess whether a subject is at risk for developing a disease or to identify a set of SNP alleles associated with a disease. The method can also be used to perform linkage analysis. AAASS944 to AAASS947 represent to AAASS632 represent nucleotide sequences containing SNPs.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Detection of single nucleotide polymorphisms in genomes by preparation and analysis of reduced complexity genomes, useful for genotyping, fingerprinting and determining allele frequency of SNPs
                                                                                                                                                                                                                                                   Human; single nucleotide polymorphism; SNP; genotyping; DNA analysis; allele specific oligonucleotide; ASO; reduced complexity genome; RCG; genomic classification; identification; DNA fingerprinting; tumour characterisation; hybridisation; ss.

with a target sequence and contain at least one phosphoro (di) thioate link, having endonuclease activity. (A), and more generally any catalytic nucleic acid (A') that modulates expression of the oestrogen creceptor gene, are used to treat cancer (particularly of breast or endometrium), in vivo or by transforming cells ex vivo and implanting treated cells, or for other conditions associated with levels of coestrogen receptor. Because of the high selectivity for targeted RNA, (A) can also be used to correlate inhibition of gene expression with alterations in phenotype, particularly for identification of therapeutic targets, and as research reagents (for RNA, in the combination of modifications in (A) improves resistance to nucleases, binding affinity and/first in the saction exceptor and/for activity. AAA2503 to AAA2474 represent oestrogen receptor harmerbead riboxyme sequences, and AAA25103 to AAA2510 
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ..

19-JUL-2000 (first entry)

```
The present invention describes nucleic acids (A) that interact stably with a target sequence and contain at least one phosphoro(di)thioate link, having endonuclease activity. (B), and more generally any catalytic nucleic acid (A') that modulates expression of the oestrogen ceeptor gene, are used to treat cancer (particularly of breast or receptor gene, are used to treat cancer (particularly of breast or conductions associated with levels of centrogen receptor. Because of the high selectivity for targeted RNA, (A) can also be used to correlate inhibition of gene expression with carteriors in phenotype, particularly for identification of therapeutic targets, and as research reagents (for RNA, in the same way that restriction endonucleases are used with DNA). The combination of and/or activity. AAA23503 to AAA24747 represent Oestrogen receptor. Cand/or activity, AAA23503 to AAA24748 to AAA25992 represent their corresponding target sequences, and AAAA26105 represent their receptor hairpin ribozyme sequences, and AAA26105 represent cestrogen receptor receptor hairpin ribozyme sequences, and AAA26107 to AAA25992 represent their thair corresponding target sequences. AAA25993 to AAA25197 to AAA25992 represent their thair corresponding target sequences. AAA25993 to AAA25197 to AAA25992 represent their thair corresponding target sequences. AAA25993 to AAA25197 to AAA25992 represent their thair corresponding target sequences. AAA25993 to AAA25197 to AAA25993 represent their thair corresponding target sequences. AAA25993 to AAA25197 to AAA25993 represent their thair corresponding target sequences and AAA25197 to AAA25993 represent their thair corresponding target sequences. AAA25993 to AAA259
                                                                                                                                                           Oestrogen receptor hammerhead ribozyme target sequence SEQ ID NO:1679.
                                                                                                                                                                                                               Oestrogen receptor; c-raf; k-ras; bcl-2; ribozyme; cleavage; hammerhead ribozyme; hairpin ribozyme; antisense oligonucleotide; paneression modification; cancer; phosphorothioate; endonuclease; anticancer; breast cancer; endometrium cancer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              their corresponding target sequences. AAA26219 to AAA26271 represent other ribozyme sequences and antisense oligonucleotides used in the exemplification of the present invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 New nucleic acids that interact, and optionally cleave, target
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Sequence 17 BP; 1 A; 0 C; 2 G; 14 T; 0 other;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     McSwiggen JA,

with a target sequence and contain at least one phosphoro (di) thicoster link, having endomuclease activity. (A), and more generally any catalytic nucleic acid (A') that modulates expression of the oestrogen receptor gene, are used to treat cancer (particularly of breast or endometrium), in vivo or by transforming cells at vivo and implanting tracted cells, or for other conditions associated with largeted RNA, (A) estrogen receptor. Because of the high selectivity for targeted RNA, alterations in phenotype, particularly for identification of the respects, and as research reagents (for RNA, in the same way that restriction endonucleases are used with DNA). The combination of modifications in (A) improves resistance to nucleases, binding affinity and/or activity. AAAA3503 to AAAA4747 represent oestrogen receptor hammerhead riboxyme sequences, and AAAA4748 to AAAA5592 represent their
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   corresponding target sequences. AAA25993 to AAA26105 represent oestrogen receptor hairpin ribozyme sequences, and AAA26107 to AAA26218 represent their corresponding target sequences. AAA26219 to AAA26271 represent other ribozyme sequences and antisense oligonucleotides used in the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The present invention describes nucleic acids (A) that interact stably

```

Retinoblastoma mutation correcting oligonucleotide SEQ ID NO: 599.

=

```
with a target sequence and contain at least one phosphoro(di)thicate link, having endounclease activity. (A), and more generally any catalytic mucleic acid (A') that modulates expression of the oestrogen receptor gene, are used to treat cancer (particularly of breast or candentium), in vivo or by transforming cells ex vivo and implanting treated cells, or for other conditions associated with levels of cestrogen receptor. Because of the high selectivity for targeted RNA, (A) can also be used to correlate inhibition of gene expression with cargets, and as research reagents (for RNA, in the same way that targets, and as research reagents (for RNA, in the combination of modifications in (A) improves resistence to nucleases, binding affinity and/or activity. AAA23503 to AAA43747 represent oestrogen receptor commenced in their commenced in the sequences, and AAA4748 to AAA2592 represent their
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 corresponding target sequences. AAA25993 to AAA26105 represent oestrogen receptor hairpin ribozyme sequences, and AAA36107 to AAA36219 represent their corresponding target sequences. AAA26219 to AAA26271 represent other ribozyme sequences and antisense oligonucleotides used in the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                present invention describes nucleic acids (A) that interact stably
                                                                                  Oestrogen receptor hammerhead ribozyme target sequence SEQ ID NO:1954
                                                                                                                                             Oestrogen receptor; c-raf; k-ras; bcl-2; ribozyme; cleavage; hammerhead ribozyme; hairpin ribozyme; antisense oligonucleotide; gene expression modification; cancer; phosphorothioate; endonuclease;

Oligonucleotide for targeted alterations of genetic sequences and for treating cystic fibrosis, comprises at least one mismatch and chemical

Claim 7; Page 80; 294pp; English.

The present invention provides single-stranded oligonucleotides which can be used for the targeted alteration of genomic sequences, where the oligonucleotide has at least one mismatch compared with the genomic sequence to be altered. In particular, these sequences are directed at the following genes: adenosine deaminase, p53, beta-globin, retinoblastoma, BRCA1, BRCA2, CFTR, cyclin-dependent kinase inhibitor 2A (CDKN2A), APC, Factor V, Factor VIII, Factor IX, heamoglobin alpha locus (CDKN2A), APC, Factor V, Factor VIII, Factor IX, heamoglobin alpha locus (CDLR), UDP-glucuronosyltransferase (UGTA1), amyloid precursor protein (LDLR), UDP-glucuronosyltransferase cuch as cancer, adenosine deaminase deficiency, cystic fibrosis, haemophilia, hypercholesterolaemia, thalassaemia, sickle cell anaemia, hypersholmer's disease, melanoma, adenomatous polyposis of the colon and various syndromes. The present sequence is one of the gene correcting oligonucleotides of the invention.

Oligonucleotide for targeted alterations of genetic sequences and for treating cystic fibrosis, comprises at least one mismatch and chemical modification -

Claim 7; Page 80; 294pp; English.

The present invention provides single-stranded oligomucleotides which can be used for the targeted alteration of genomic sequences, where the oligomucleotide has at least one mismatch compared with the genomic sequence to be altered. In particular, these sequences are directed at the following genes: adenosine deaminase, p53, beta-globin, retinoblastoma, BRCA1, grK, cyclin-dependent kinase inhibitor 2A (CDKNA2), APC, Factor VIII, Factor IX, haemoglobin alpha locus apolipoprotein E (APOR), LDL receptor (LDLR), UDP-glucuronosyltransferase (UGT1), amyloid precursor protein (APC), presentlin-1 (PSENI) and presentlin-2 (PSENI). These can be used in the gene therapy of diseases such as cancer, adenosine deaminase deficiency, cystic fibrosis, cancer, adenosine deaminase deficiency, cystic fibrosis, lilia, hypercholesterolaemia, thalassaemia, sickle cell anaemia, st disease, melanoma adenomatcus polyposis of the colon and syndromes. The present sequence is one of the gene correcting oligonucleotides of the invention. haemophilia, Alzheimer's various

Agent for correcting gene expression regulation error comprises pyrone compound or dihydroxy compound

Example 4; Page 61; 93pp; Japanese.

The interaction provides an agent compound of specified formulae give in the specification. The agent is used for correcting gene expression regulation errors. Errors in the following genes may be corrected: IL-6, IL-10, hemeoxygenase-1, prostaglandin G/H synthase-2, macrophage inflammatory protein-1-alpha, RANTES, IL-1alpha, IL-1beta, TNF alpha, IL-7 receptor, macrophage for macrophage derived chemokine, macrophage derived chemokine, macrophage inflammatory protein-1-alpha, macrophage inflammatory protein-2-lapha, growth regulated protein-1, matrix metalloproteinase-9, migration inhibitory factor-related protein-1, early proxes, GABA(A) receptor-associated protein, interferon-inducible protein p79, SCO homolog-2, transketolase, adenosine A2a receptor, CD37 antigen properdin P factor, regulator of G-protein signaling-2, Nef-associated factor-1, myeloid also side-effects caused by them such as inflammation. Sequences The invention provides an agent comprising a pyrone compound or dihydroxy

                                                                                                                                                                                                                                                ₽
                                                                                                                                                                                                                                                                                                                                                                                                                     ö
                                                                                                                                                                                                                                                                                               The present invention provides nucleic acid molecules capable of downregulating the expression of the human checkpoint kinase-1 (Chkl) gene. These may be antisense or ribozyme sequences, and are useful in the treatment of diseases associated with conditions affected by Chkl levels, including cancer. The present sequence is an oligonucleotide described in the exemplification of the invention.
                                                                                                                                                                                                                     Novel nucleic acid molecule e.g., ribozymes or antisense nucleic acid molecules, which downregulates expression of a checkpoint kinase-1 gene, useful for treating colorectal, lung, breast or prostate cancers
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 checkpoint kinase-1; Chk1; antisense; ribozyme; gene therapy;

```
The present invention provides nucleic acid molecules capable of downregulating the expression of the human checkpoint kinase-1 (Chkl) gene. These may be antisense or ribozyme sequences, and are useful in the treatment of diseases associated with conditions affected by Chkl levels, including cancer. The present sequence is an oligonucleotide described in the exemplification of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                The present invention provides nucleic acid molecules capable of downregulating the expression of the human checkpoint kinase-1 (Chkl) gene. These may be antisense or ribozyme sequences, and are useful in the treatment of diseases associated with conditions affected by Chkl levels, including cancer. The present sequence is an oligonucleotide described in the exemplification of the invention.
                                  Novel nucleic acid molecule e.g., ribozymes or antisense nucleic acid molecules, which downregulates expression of a checkpoint kinase-1 gene, useful for treating colorectal, lung, breast or prostate cancers
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   molecules, which downregulates expression of a checkpoint kinase-1 gene, useful for treating colorectal, lung, breast or prostate cancers
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Novel nucleic acid molecule e.g., ribozymes or antisense nucleic acid
                                                                                                                                                                                                                                                                                                                                                                                          Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The present invention describes a method for predicting the potential of an oligonucleotide to hybridise to a (complementary) target nucleotide sequence, involving identifying a subset of oligonucleotides within the predetermined number of unique oligonucleotides based on the evaluation of the parameter. Oligonucleotides in the subset are identified that are clustered along a region of the nucleotide sequence that is hybridisable to the target nucleotide sequence. This is useful for evaluating oligonucleotide probe sequences. This present sequence is an oligonucleotide described in the exemplification of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Predicting the potential of an oligonucleotide to hybridize to a target nucleotide sequence, useful for evaluating oligonucleotide probe sequences, by identifying a oligonucleotides based on the evaluation of parameters

The cell cycle checkpoints are regulatory pathways that control the order and timing of cell cycle transitions, and ensure that critical events such as DNA replication and chromosome segregation are completed with high fidelity. The chti protein controls cell cycle in response to DNA damage. It functions as kinase and phosphorylates the key regulators of Cdk tyrosine phosphorylation. The checkpoint gene sequences are used as probes for a portion of the chromosome associated with unmours and other malignancies, as well as growth and/or development deficiencies. The chkin proteins are useful for generating specific antibodies and for inhibiting

(BLAT/)

The invention relates to a nucleic acid molecule which down regulates expression of a CD20 gene and a nucleic acid molecule which down regulates expression of a neurite growth inhibitor gene (NGCO).

The nucleic acids may be enzymatic nucleic acids (e.g. a ribozyme or a possessing an NCH moutif), a cleaver (cleaving RNA with a NRN molecule possessing an NCH moutif), a G-cleaver (cleaving RNA with a NRN molecule cleaving RNA with a NRN molecule possessing an NCH moutif).

CC Cleave RNA of CD20 in the presence of a divalent cation that is preferably MG·2+. Furthermore, it may be contacted with a cell to reduce CD20 activity of the cell and treat a patient having a condition correct considerable with the level of CD20. The treatment may further comprise the classociated with the level of CD20 treat lymphoma, leavening, B-cell of CD20 treat lymphoma, leavening, B-cell of CD20 treat lymphocytic laukaemia, B-cell of CD20 treat lymphoma (NHL), bulky low-grade or follicular NHL, lymphocytic laukaemia, HTV (human immunodeficiency virus) associated NHL, mantle-cell lymphoma (NHL), university of the NOGO gene in the presence of divalent cation that is preferably Mg·2+. Furthermore, the nucleic acid may be contacted with a cell to reduce NOGO gene in the presence of divalent cation that is preferably Mg·2+. Furthermore, the nucleic acid may be used to cleave RNA of the NOGO gene in the presence of divalent cation that is preferably Mg·2+. Furthermore, the nucleic acid may be used to create (CC may be contacted with a cell to reduce NOGO activity of the cell and treat a patient having a condition associated with the level of NOGO. Exertical nervous system (CNS) injury and cerebroascular accident (CVA, stroke), Alzheimer's disease, dementia, multiple sclerosis (MS), chemic brazapi-induced neuropathy, amyotrophic lateral sclerosis (MS), Parkinson's disease, ataxia, Huntington's disease, create mediate may induced neuropathy, and/or other neurodegenerative disease demented is an incorrect rectain of NGCO experimented is an inc chemotherapy-induced neuropathy; amyotrophic lateral sclerosis; ALS; Parkinson's disease; ataxia; Huntington's disease; Creutzfeldt-Jakob disease; muscular dystrophy; neurodegenerative disease. Nucleic acid molecules, e.g., enzymatic nucleic acids and antisense constructs, which down regulate expression of a CD20 gene or neurite growth inhibitor gene useful for treating, e.g., lymphoma, leukemia, and central nervous system injury present sequence is an inozyme of the invention. ```
The invention relates to a nucleic acid molecule which down regulates expression of a CD20 gene and a nucleic acid molecule which down regulates expression of a neurite growth inhibit or gene (NGGO).

The nucleic acids may be enzymatic nucleic acids (e.g. a ribozyme or a DNAzyme) an Inozyme (an endolytic nucleic acids (e.g. a ribozyme or a DNAzyme) an Inozyme (an endolytic nucleic acid cleaving an RNA molecule (cleaving an NCH motif), a G-cleaver (cleaving RNA with a NXN molecule (cleaving RNA with a YGY motif). The CD20-targetting nucleic acid is used to cleave RNA of CD20 in the presence of a divalent cation that is preferably Mg2 4. Furthermore, it may be contacted with a cell to reduce CD20 activity of the cell and treat a patient having a condition associated with the level of CD20. The treatment may further comprise the cuse of one or more therapies. In particular, the CD20 targetting nucleic acid may be used to treat lymphoma, leukaemia, B-cell lymphocytic leukaemia, HIV (human, lymphocytic leukaemia, HIV (human, lymphocytic leukaemia, HIV (human, lymphocytic leukaemia, HIV) (human, lymphocytic leukaemia, HIV (human, lymphocytic leukaemia, HIV (human, lymphocytic leukaemia, HIV) (lymphocytic leukaemia, HIV) (lymphocytic leukaemia, HIV) (lymphocytic leukaemia, HIV
                                                                                                                                                                                                                                                                                                                                                                                                                cerebroprotective, nootropic; neuroprotective; antiparkinsonian; muscular; CD20; neurite growth inhibitor gene; NOGO; hammerhead ribozyme; DNAzyme; inozyme; dD20; neurite growth inhibitor gene; NOGO; hammerhead ribozyme; B-cell lymphome; d-cleaver; amberryme; lymphoma; leukaemia; B-cell lymphoma; non-Bodgkin; slymphoma; MRL; lymphocytic leukaemia; MCL; immunodeficiency virus; HIV associated NHL; mantle-cell lymphoma; MCL; immunocytoma; IMC; immune thrombocytopaenia; stroke; dementia; inflammatory arthropathy; central nervous system injury; cerebrovascular accident; CVA; Alzheimer's disease; multiple sclerosis; chemotherapy-induced neuropathy; amyotrophic lateral sclerosis; ALS; Parkinson's disease; ataxia; Huntington's disease; creutzfeldt-Jakob disease; muscular dystrophy; neurodegenerative disease.
                                                                                                                                                                                                                                                                                                                                                                                         Human; 88; antisense therapy; cytostatic; antiinflammatory; haemostatic;

immunocytoma (IMC), small B-cell lymphocytic lymphoma, immune thrombocytopaenia, and inflammatory arthropathy. The NoGO-targetting nucleic acid is used to cleave RNA of the NoGO gene in the presence of a divalent cation that is preferably Mo^2+. Furthermore, the nucleic acid divalent cation that is preferably Mo^2+. Furthermore, the nucleic acid may be contacted with a cell to reduce NoGO activity of the cell and creat a patient having a condition associated with the level of NoGO. The treatment may further comprise the use of one or more therapies.

In particular, the NoGO-targetting nucleic acid may be used to treat central nervous system (CNS) injury and cerebrovascular accident (CNA, stroke), Alzheimer's disease, dementia, multiple sclerosis (MS), chemotherapy-induced neuropathy, amyotrophic lateral sclerosis (MS), arkingson's disease, ataxia, Huntington's disease, Creutzfeldt-Jakob disease, muscular dystrophy, and/or other neurodegenerative disease states which respond to the modulation of MoGO expression. The present sequence is an inozyme of the invention.

Nucleic acid molecules, e.g., enzymatic nucleic acids and antisense

The invention relates to a nucleic acid molecule which down regulates expression of a CD20 gene and a nucleic acid molecule which down regulates expression of a neurite growth inhibitor gene (NGCO).

Tregulates expression of a neurite growth inhibitor gene (NGCO).

The nucleic acids may be enzymatic nucleic acids (e.g. a ribozyme or a DNAzyme) an Inozyme (an endolytic nucleic acid cleaving RNA with a NYN molecule possessing an NCH motif), a G-cleaver (cleaving RNA with a NYN riplet), a zinzyme (cleaving RNA with a YGY motif). The CD20 -targetting nucleic acid is used to cleave RNA of CD20 in the presence of a divalent cation that is preferably MG'2+. Furthermore, it may be contacted with a cell to reduce CD20 activity of the cell and treat a patient having a condition associated with the level of CD20. The treatment may further comprise the contact may be used to treat lymphoma, leukaemia, B-call bulky use of one or more therapies. In particular, the CD20 targetting invented or follicular NHL, lymphocytic leukaemia, HIV (human immunocation or follicular NHL, lymphocytic leukaemia, HIV (human immunocation acid may be used to real lymphocytic lymphoma, induced or follicular NHL, lymphocytic lymphoma, induced acid is used to cleave RNA of the NOGO gene in the presence of divalent cation that is preferably MG'2+. Furthermore, the nucleic acid is used to cleave RNA of the NOGO gene in the presence of a divalent cation that is preferably MG'2+. Furthermore, the nucleic acid may be contacted with a cell to reduce NOGO activity of the cell and may further comprise the use of one or more therapies.

The particular, the NOGO-targetting nucleic acid may be used to treat central nervous system (CNS) injury and cerebroxascular accident (CNS) intoxy and cerebroxascular accident (CNS) intoxy and cerebroxascular accident (CNS) intoxy and cerebroxascular accident (CNS) farrice) attacks). All Anchimer Sudserse, demential, multiple selectoris (MG).

The particular is genese, demential, multiple selectoris (MG).

The particular is constructs, which down regulate expression of a CD20 gene or neurite growth inhibitor gene useful for treating, e.g., lymphoma, leukemia, and central nervous system injury Claim 88; Page 99; 200pp; English.

```
The invention relates to a nucleic acid molecule which down regulates expression of a CD20 gene and a nucleic acid molecule which down regulates expression of a neutrite growth inhibitor gene (MOGO).

Tregulates expression of a neutrite growth inhibitor gene (MOGO).

The nucleic acids may be enzymatic nucleic acid cleaving an RNA molecule possessing an NCH motif). A G-cleaver (cleaving RNA with a NNN molecule coid prospersion and motified and motified acid is used to cleave RNA of CD20 in the presence of a divalent cation that is closed with the level of CD20 in the presence of a divalent cation that is closed with the level of CD20 in the presence of a divalent capitor reduce to coleave RNA of CD20 in the presence of a divalent capitor reduce coleave RNA of CD20 in the presence of a divalent capitor of CD20 activity of the cell and treat a patient having a condition associated with the level of CD20. In particular, the CD20 targetting nucleic acid may be used to treat lymphoma, leukaemia, B-Cell inpubnam, leukaemia, AD20 targetting nucleic acid may be used to treat lymphocytic leukaemia, HIV (human immunocytoma (IMC), small B-Cell liquatory arthropathy. The NOGO-targetting nucleic acid is used to cleave RNA of the NOGO gene in the presence of a divalent cation that is preserably M3 24. Furthermore, the nucleic acid may be contacted with a cell to reduce NOGO activity of the cell and treat a patient having a condition associated with the level of NOGO. The treatment may further comparise the use of one or more therapies.

The particular, the NOGO-targetting nucleic acid may be used to treat central nervous system (CNS) injury and crebrovascular accident (CNA, strand) and/or other neutrodegenerative disease tears, Huntington's disease, amaxia, Huntington's disease, acan's Huntington's disease, muscular dystrophy, and/or other neutrodegenerative disease teases which respond to the modulation of NOGO expression. The present sequence is a zinzyme molecule of the number of the number of the number of the number of t
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Nucleic acid molecules, e.g., enzymatic nucleic acids and antisense constructs, which down regulate expression of a CD20 gene or neurite growth inhibitor gene useful for treating, e.g., lymphoma, leukemia,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Sequence 17 BP; 2 A; 6 C; 2 G; 7 U; 0 other;

Chowrira BM;

Nucleic acid molecules, e.g., enzymatic nucleic acids and antisense constructs, which down regulate expression of a CD20 gene or neurite growth inhibitor gene useful for treating, e.g., lymphoma, leukemia, and central nervous system injury

Claim 88; Page 134; 200pp; English.

The invention relates to a nucleic acid molecule which down regulates expression of a CD20 gene and a nucleic acid molecule which down regulates expression of a neurite growth inhibitor gene (NGCO).

The nucleic acids may be enzymatic nucleic acids (e.g. a ribozyme or a DNAzyme) an Inozyme (an endolytic nucleic acid cleaving a an RNA molecule possessing an NCH motif), a G-cleaver (cleaving RNA with a NRN molecule collism and an amberzyme (cleaving RNA with a NRN molecule colleaving RNA with a NGN motif). The CD20-targetting nucleic acid is used to cleaving NA with a relation that is preferably MG'2²+. Furthermore, it may be contacted with a cell to reduce collected with the level of CD20. The treatment may further comprise the cuse of one or more therapies. In particular, the CD20 targetting cuse of one or more therapies. In particular, the CD20 targetting cuse of collicular NH1, lymphocytic leukaemia, B-cell collow-grade or follicular NH1, lymphocytic leukaemia, HIV (human (MCL), immunodeficiency virus) associated NH1, mantle-cell lymphoma (MCL), climunocytoma (IMC), small B-cell lymphocytic lymphoma, immune collicular nh1, lymphocytic lymphoma, immune collicular nh2 inflammatory arthropathy. The NOGO-targetting cuncleic acid is used to cleave RNA of the NOGO gene in the presence of a divalent cation that is preferably Mg^2++. Furthermore, the nucleic acid

may be contacted with a cell to reduce NOGO activity of the cell and treat a patient having a condition associated with the level of NOGO. The treatment may further comprise the use of one or more therapies.

In particular, the NOGO-targetting nucleic acid may be used to treat central nervous system (ONS) injury and cerebrovascular accident (CVA, stroke), Alzheimer's disease, dementia, multiple sclerosis (MS), parkinson's disease, ataxia, Huntington's disease, Creutzfeldt-Jakob disease, muscular dystrophy, and/or other neurodegenerative disease states which respond to the modulation of NOGO expression. The present sequence is an amberzyme molecule of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        cerebroprotective, nootropic, neuroprotective, antiparkinsonian; muscular; CD20; neurice growth inhibitor gene; NOGO; hammerhead ribozyme; DNAzyme; incyyme; G-cleaver; amberzyme; zinzyme; lymphoma; leukaemia; B-cell lymphoma; non-Hodgkin's lymphoma; MHL; lymphocytic leukaemia; McL; immunodeficiency virus; HV associated NHL; mantle-cell lymphoma; MCL; immunocytoma; IMC; immune thrombocytopaenia; stroke; dementia; inflammatory arthropathy; central nervous system injury; cerebrovascular accident; CVA; Alzheimer's disease; multiple sclerosis; chemotherapy-induced neuropathy; ampotrophic lateral sclerosis; ALS; parkinson's disease; ataxia; Huntington's disease; creutzfeldt-Jakob disease; muscular dystrophy; neurodegenerative disease.

The invention relates to a nucleic acid molecule which down regulates expression of a meurite growth inhibitor good.

Tegulates expression of a neurite growth inhibitor good.

Tegulates expression of a neurite growth inhibitor good.

The nucleic acids may be enzymatic nucleic acids (e.g. a ribozyme or a DRAzyme) an Inozyme (an endolytic nucleic acids (e.g. a ribozyme or a DRAzyme) an Inozyme (cleaving RNA with a NVN molecule possessing an NCH motif), a G-cleaver (cleaving RNA with a NVN molecule cleaving RNA with a NYN molecule ocid cleaving RNA with a NYN molecule ocid activity of the cleaving RNA with an NGN triplet), a zinzyme (Cleaving RNA with a NYN molecule ocid activity of the cell and treat a patient having a condition of preferably Ng^2+. Furthermore, it may be contacted with a cell to reduce CC CD2 activity of the cell and treat a patient having a condition of CD2 in the presence of a divalent cation that is send of CD2 or theat lymphoma, the CD2 targetting or nucleic acid may be used to treat lymphoma, impured a condition of Invalent ocid in the presence of a immunocytoma (INC), small B-cell lymphocytic leukaemia, HIV (human immunodeficiency virus) associated NHL, mantle-cell lymphoma (NCL), immunocytoma (INC), small B-cell lymphocytic lymphoma, immune the Invale of NCC invalent cation that is preferably Mg^2+. Furthermore, the nucleic acid may be contacted with a cell to reduce NOGO gene in the presence of a divalent cation that is preferably Mg^2+. Furthermore, the nucleic acid may be used to treat central nervous system (CNS) injury and cerebrovascular accident (CNR, stroke), Alabeimer's disease, dementia, multiple sclerosis (MS), chemocherapy-induced neuropathy, and ocethoragenerative disease, dementia, multiple sclerosis (MS), parkinson's disease, muscular disease, dementia, multiple sclerosis (MS), parkinson's disease, muscular disease
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ó
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              PAPP-E; human; pregnancy associated plasma protein E; abortive; contraceptive; gene therapy; vaccine; pregnancy; antenatal; diagnosis; dysgenetic pregnancy; primer; ss.

activity and can be used for gene therapy or in a vaccine. The nucleic acid, polypeptide encoded by it, or antibody to the polypeptide can be used in pharmaceutical compositions or vaccines for preventing or aborting pregnancy. PAPP-E is used in the antenatal diagnosis of dysgenetic pregnancies. The nucleic acids are used as probes to assess the level of PAPP-E isoform mRNA in chorionic villus samples, and the antibodies can be used to assess the expression levels of PAPP-E isoform antibodies can be used to assess the copression levels of PAPP-E isoform proteins in chorionic villus samples, to diagnose dysgenetic pregnancies antenatally. This sequence reperseents an oligomer used in scanning the human PAPP-E genes described in the disclosure of the invention.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ö
                                                                                                                                                                                                              one of three new isoforms of human pregnancy associated plasma protein E, hPAPP-E. The products of the invention have abortive and contraceptive activity and can be used for gene therapy or in a vaccine. The nucleic acid, polypeptide encoded by it, or attibody to the polypeptide can be used in pharmaceutical compositions or vaccines for preventing or aborting pregnancy. PAPP-E is used in the antenatal diagnosis of dysgenetic pregnancies. The nucleic acids are used as probes to assess the level of PAPP-E isoform mRNA in chorionic villus samples, and the antibodies can be used to assess the expression levels of PAPP-E isoform proteins in chorionic villus samples, to diagnose dysgenetic pregnancies antenatally. This sequence repersents an oligomer used in scanning the human PAPP-E genes described in the disclosure of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       PAPP-E; human; pregnancy associated plasma protein E; abortive; contraceptive; gene therapy; vaccine; pregnancy; antenatal; diagnosis; dysgenetic pregnancy; primer; ss.

protein I (POSHL I) polypeptide (I), comprising a sequence of 730 amino acids (S1, ABBB3999), a sequence having 65% sequence identity to (S1), (S1) having 95% deviations, especially conservative substitutions or a fragment of the sequences comprising at least 8 contiguous amino acids. Human POSHL 1 is a proto-oncogene/oncogene product that functions as an

ы

The invention relates to an isolated SH3 domain (POSH)-like signalling

Example 2; SEQ ID NO 1670; 60pp + Sequence Listing; English.

                                                                                                                                                                                                                                                                                                                                                                                           ;
adaptor protein that interacts with Rho family small GTPases as well as downstream components of the signal transduction pathway. (I) is useful for identifying a specific binding pattner. (I) and nucleic acids (II) encoding (I) are useful for diagnosing, monitoring disease and treating caused by altered expression of human PoSHLI including diagnosing and treating cancer, they useful in the development of vaccines and (II) is useful in gene therapy. (II) is useful for constructing microarrays which are useful for measuring and for surveying gene expression and creating transgenic non-human animals capable of producing the proteins. The
                                                                                                                         Note: The present sequence did not form part of the printed specification, but is based on sequence information supplied to Derwent
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The invention relates to an isolated SH3 domain (POSH)-like signalling protein 1 (POSHL 1) polypeptide (1), comprising a sequence of 730 amino

acids (S1, ABB33999), a sequence having 65% sequence identity to (S1),

(S1) having 95% deviations, especially conservative substitutions or a
fragment of the sequences comprising at least 8 contiguous anino acids.

Human POSHL 1 is a proto-oncogene product that functions as an
adaptor protein that interacts with Rho family small GTPases as well as
downstream components of the signal transduction pathway. [I] is useful
for identifying a specific binding partner. [I) and nucleic acids [II]
encoding [I] are useful for diagnosing, monitoring disease and treating
caused by altered expression of human POSHL1 including diagnosing and
treating cancer, they useful in the development of vaccines and [II] is
useful in gene therapy. [II] is useful for constructing microarrays which
are useful for measuring and for surveying gene expression and creating
transgenic non-human animals capable of producing the proteins. The
present sequence is that of a scanning oligonucleotide useful in examples
of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          ö

KTOM1 (kidney tumour overexpressed membrane) protein. The protein of the invention has eytostatic activity. The nucleotide may have a use in gene therapy. The KTOM1 nucleic acids may be used to diagnose, treat or monitor a disease caused by altered expression of human KTOM1. Compositions comprising the nucleic acids, proteins or antibodies may be used to treat subjects having defects in KTOM1 which can manifest as cancer of the kidney, as well as a disorder of liver, bone marrow, brain, heart, lung, kidney, colon, skeletal muscle, testis, uterus and placenta scan the nt 1-1001 portion of human KTOM1a (ABG63232).
                                                      New human kidney tumor overexpressed membrane (KTOM1) protein and nucleic acids encoding the protein, useful for treating subjects having defects in KTOM1 which can manifest as cancer of the kidney, or as a

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ô
                                                                                                                                                                                                        The invention relates to a novel isolated nucleic acid encoding human KTOM1 (kidney tumour overexpressed membrane) protein. The protein of the invention has cytostatic activity. The nucleotide may have a use in gene therapy. The KTOM1 nucleic acids may be used to diagnose, treat or monitor a disease caused by altered expression of human KTOM1. Compositions comprising the nucleic acids, proteins or antibodies may be used to treat subjects having defects in KTOM1 which can manifest as cancer of the kidney, solen as well as a disorder of liver, bone marrow, brain, heart, lung, kidney, colon, skeletal muscle, testis, uterus and placenta function. The sequence represents a probe used in the invention to scan the nt 1-1001 portion of human KTOM1a (ABQ63232).
      New human kidney tumor overexpressed membrane (KTOMI) protein and nucleic acids encoding the protein, useful for treating subjects having defects in KTOMI which can manifest as cancer of the kidney, or as a disorder of e.g., liver or bone
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Gaps

KTOMI (kidney tumour overexpressed membrane) protein. The protein of the invention has cytostatic activity. The nucleotide may have a use in gene therapy. The KTOMI nucleic acids may be used to diagnose, treat or monitor a disease caused by altered expression of human KTOMI. Compositions comprising the nucleic acids, proteins or antibodies may be used to treat subjects having defects in KTOMI which can manifest as cancer of the kidney, as well as a disorder of liver, bone marrow, brain, heart, lung, kidney, colon, skeletal muscle, testis, uterus and placenta scan the nt 1-1001 portion of human KTOMIa (ABQ63232).
                                                    nucleic acids encoding the protein, useful for treating subjects having defects in KTOM1 which can manifest as cancer of the kidney, or as a

                                                                                                                                                                                                                                                The invention relates to a novel isolated nucleic acid encoding human KTOM1 (kidney tumour overexpressed membrane) protein. The protein of the invention has cytostatic activity. The nucleotide may have a use in gene therapy. The KTOM1 nucleic acids may be used to diagnose, treat or monitor a disease caused by altered expression of human KTOM1.

Compositions comprising the nucleic acids, proteins or antibodies may be used to treat subjects having defects in KTOM1 which can manifest as cancer of the kidney, as well as a disorder of liver, bone marrow, brain, heart, lung, kidney, colon, skeletal muscle, testis, uterus and placenta function. The sequence represents a probe used in the invention to scan the nt 1-1001 portion of human KTOM1a (ABQ653232).
                                                                                    New human kidney tumor overexpressed membrane (KTOM1) protein and nucleic acids encoding the protein, useful for treating subjects having defects in KTOM1 which can manifest as cancer of the kidney, or as a

                                                                                                                                                                                                                                                                                                                                                                                                                     ö
The invention relates to a novel isolated nucleic acid encoding human KTOM1 (kidney tumour overexpressed membrane) protein. The protein of the thrownton has cytostatic activity. The nucleotide may have a use in gene therapy. The KTOM1 nucleic acids may be used to diagnose, treat or monitor a disease caused by altered expression of human KTOM1. Compositions comprising the nucleic acids, proteins or antibodies may be used to treat subjects having defects in KTOM1 which can manifest as cancer of the kidney, as well as a disorder of liver, bone marrow, brain, heart, lung, kidney, colon, skeletal muscle, teetis, uterus and placenta function. The sequence represents a probe used in the invention to scan the nt 1-1001 portion of human KTOM1a (ABQ63232).

The invention relates to a novel isolated nucleic acid encoding human KTOM1 (kidney tumour overexpressed membrane) protein. The protein of the invention has cytostatic activity. The nucleotide may have a use in gene therapy. The KTOM1 nucleic acids may be used to diagnose, treat or monitor a disease caused by altered expression of human KTOM1.

Compositions comprising the nucleic acids, proteins or antibodies may be used to treat subjects having defects in KTOM1 which can manifest as cancer of the kidney, as well as a disorder of liver, bone marrow, brain, heart, lung, kidney, colon, skeletal muscle, testis, uterus and placenta function. The sequence represents a probe used in the invention to scan the nt 1-1001 portion of human KTOM1a (ABQ631232).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    antiinflammatory; chronic obstructive pulmonary disease; COPD; asthma; chronic bronchitis; cystic fibrosis; obstructive bowel syndrome; oxygen therapy; bronchodilator; corticosteroid; vaccination; mucokinetic;
                                                                                                      New human kidney tumor overexpressed membrane (KTOMI) protein and nucleic acids encoding the protein, useful for treating subjects having defects in KTOMI which can manifest as cancer of the kidney, or as a disorder of e.g., liver or bone
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Enzymatic polynucleotide that down regulates expression of chloride channel calcium activated gene, useful for treating Chronic obstructive

pulmonary disease (COPD), chronic bronchitis and asthma
```

```
Claim 4; Page 79; 152pp; English.
```

The invention relates to enzymatic nucleic acid molecules that down required expression of chloride channel calcium activated 1 (CLCA1) genes by cleaving RNA derived from the genes. The nucleic acid sequences are useful as pharmaceutical agents for treating conditions such as chronic constructive pulmonary disease (COPD), chronic bronchitis, asthma, cystic fibrosis, obstructive bowel syndrome and any other diseases or conditions that are related to or will respond to the levels of CLCA1 in a cell, chence, are useful for treatment of a patient having a condition cals when the level of CLCA1, where the invention further comprises the use of one or more therapies under conditions suitable for the treatment, for example, oxygen therapy, bronchodilators, corticosteroids, antibacterials, vaccinations, acetylcysteine and mucokinetic agents. The mucleic acids of the invention are also used as diagnostic tools to cammine genetic drift and mutations within diseased cells or to detect the presence of CLCA1 RNA in a cell. This sequence represents an exymatic nucleic acid molecule of the invention.

The nucleic acids of the invention are also used as diagnostic tools to examine genetic drift and mutations within diseased cells or to detect the presence of CLCA1 RNA in a cell. This sequence represents an enzymatic nucleic acid molecule of the invention.
                                                                                                                                                                                                                                                                                                                                                                    Gaps

Enzymatic polynucleotide that down regulates expression of chloride channel calcium activated gene, useful for treating Chronic obstructive pulmonary disease (COPD), chronic bronchitis and asthma -

Claim 4; Page 135; 152pp; English.

The invention relates to enzymatic nucleic acid molecules that down regulate expression of chloride channel calcium activated 1 (CLCA1) genes by cleaving RNA derived from the genes. The nucleic acid sequences are useful as pharmaceutical agente for treating conditions such as chronic obstructive pulmonary disease (COPD), chronic bronchitis, asthma, cystic fibrosis, obstructive bowel syndrome and any other diseases or conditions that are related to or will respond to the levels of CLCA1 in a cell or tissue. The sequences are useful for reducing CLCA1 activity in a cell,

and pan-endothelial markers (PEM) ABL91903-ABL91995. The present sequence is that of an oligonucleotide marker useful to the invention.

hence, are useful for treatment of a patient having a condition associated with the level of CLCAI, where the invention further comprises the use of one or more therapies under conditions suitable for the treatment, for example, oxygen therapy, bronchodilators, corticosteroids, antibacterials, vaccinations, acetylcysteine and mucokinetic agents. The nucleic acids of the invention are also used as diagnostic tools to examine genetic drift and mutations within diseased cells or to detect the presence of CLCAI RNA in a cell. This sequence represents an enzymatic nucleic acid molecule of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                     Human; mouse; rat; TEM; tumour endothelial marker; NEM; PEM; cytostatic; normal endothelial marker; jamunostimulant; antiangiogenic; tumour; neoaglogensesis; vascularised tumour; polycystic kidney disease; diabetes; retinopathy; rheumatoid arthritis;

The present invention describes a human genome-derived myosin-like protein 1 (hGDMLP-1). The protein and polymucleotide sequences of hGDMLP-1 can be used in gene therapy and vaccine production. The hGDMLP-1 mucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 mucleic acids in samples, as amplification substrates, to provide initial substrates for the recombinant engineering of hGDMLP-1 protein variants having desired phenotypic improvements, and for expressing the proteins. The hGDMLP-1 proteins or polypeptides may

The invention relates to an isolated molecule comprising an antibody variable region which specifically binds to an extracellular domain of tumour endothelial marker (TEM) protein selected from ABB9073, ABB90740, ABB90749, ABB90750 and ABB90769. The antibodies which bind to TEM proteins have cytostatic, immunostimulant and antiangiogenic activity. They are useful for inhibiting tumour growth, neonagiogenesis in subjects bearing a vascularised tumour, polycystic kidney disease, diabetic retinopathy, rheumatoid arthritis and psoriasis. Human, mouse ABB90721-ABB90789) are disclosed, as are marker oligonucleotide sequences: tumour endothelial markers (TEM) ABL91996-ABL92041 and ABL92141 and ABB92191; normal endothelial markers (NEM) ABL92042-ABL92041;

An isolated molecule comprising an antibody variable region which specifically binds to an extracellular domain of a tumor endothelial marker (TEM) protein, useful for inhibiting tumor growth -

be used as immunogens to raise antibodies that specifically recognise hGDMLP-1 proteins, as standards in assays used to determine the concentration and/or amount specifically of hGDMLP proteins, as specific biomolecule capture probes for surface-enhanced laser desorption ionisation, as therapeutic supplement in patients having specific therapy. The polymucleotide sequences encoding hGDMLP-1 may be used for the diagnosing a disorder associated with the expression of hGDMLP-1 in particular heart and skeletal muscle disorders. hGDMLP-1 is localised to chromosome 22. The present sequence represents an oligomer used in the screening of the hGDMLP-1 sequence in the exemplification of the present
                                                                                                                                                                                       N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO at ftp.wipo.int/pub/published_pct_sequence.

The present invention describes a human genome-derived myosin-like protein 1 (hGDMLP-1). The protein and polynucleotide sequences of bGDMLP-1 can be used in gene therapy and vaccine production. The hGDMLP-1 nucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 nucleic acids in samples, as amplification substrates, to provide initial substrates for the recombinant engineering of hGDMLP-1 protein variants having desired phenotypic improvements, and for expressing the proteins. The hGDMLP-1 proteins or polypeptides may be used as immunogens to raise antibodies that specifically recognise hGDMLP-1 proteins, as standards in assays used to determine the concentration and/or amount specifically of hGDMLP proteins, as specific concentration and/or amount specifically of hGDMLP proteins, as specific concentration, as therapeutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for the particular heart and skeletal muscle disorders an oligomer used in the screening of the hGDMLP-1 sequence in the exemplification of the present
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Human, genome-derived myosin-like protein 1; GDWLP-1; hGDWLP-1; heart;

The present invention describes a human genome-derived myosin-like protein 1 (hGDMLP-1). The protein and polymuclectide sequences of hardering be used in gene therapy and vaccine production. The hGDMLP-1 mucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 mucleic acids in samples, as amplification of hGDMLP-1 protein variants having desired phenotypic improvements, and cerversesing the proteins. The hGDMLP-1 protein variants having desired phenotypic improvements, and for expressing the proteins. The hGDMLP-1 proteins or polypeptides may be used as immunogens to raise antibodies that specifically recognise concentration and/or amount specifically of hGDMLP-1 proteins, as standards in assays used to determine the concentration and/or amount specifically of hGDMLP proteins, as specific concentration, as therapeutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement continuation, as therapeutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement contents of hGDMLP-1 may be used for diagnosing a disorder associated with the expression of hGDMLP-1, in patient having health muscle disorders, hGDMLP-1 may be used for cherapy. The polymucleotide sequences encoding hGDMLP-1 may be used for particular heart and skeletal muscle disorders, hGDMLP-1 in patient contents of hGDMLP-1, in contents of hGDMLP-1, in however the hGDMLP-1 sequence in the exemplification of the present in the exemplification of the present N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO at ftp.wipo.int/pub/published_pct_sequence.

New polypeptide, for raising antibodies that recognize hGDMLP-1 proteins, or as specific biomolecule capture probes for surface enhanced laser desorption ionization, comprises human myosin-like protein hGDMLP-1

Disclosure; SEQ ID 6596; 214pp; English.

The present invention describes a human genome-derived myosin-like protein 1 (hGDMLP-1). The protein and polymuclectide sequences of protein 1 (hGDMLP-1). The protein and polymuclectide sequences of maddle be used in gene therapy and vaccine production. The hGDMLP-1 nucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 modeled sin samples, as amplification constructs, the hGDMLP-1 protein variants having desired phenotypic improvements, and of rexpressing the proteins. The hGDMLP-1 proteins or polypeptides may be used as immunogens to raise antibodies that specifically recognise hGDMLP-1 proteins, as standards in assays used to determine the concentration and/or amount specifically of hGDMLP proteins, as specific concentration, as therapoutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement the achieves as therapoutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement therapy. The polymucleotide sequences encoding hGDMLP-1 may be used for therapy. The polymucleotide sequences encoding hGDMLP-1 may be used for chagnesing a disorder associated with the expression of hGDMLP-1, in particular heart and skeletal muscle disorders shopMLP-1 is localised to chromosome 22. The present sequence represents an oligomer used in the invariance in the exemplification of the present invention.

N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO at ftp.w1po.int/pub/published_pct_sequence.

hGDMLP-1 nucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 nucleic acids in samples, as amplification of provide initial substrates as amplification or substrates, to provide initial substrates for the recombinant engineering of hGDMLP-1 protein variants having desired phenotypic improvements, and for expressing the proteins. The hGDMLP-1 proteins or polypeptides may be used as immunogens to raise antibodies that specifically recognise hGDMLP-1 proteins, as standards in assays used to determine the concentration and/or amount specifically of hGDMLP proteins, as specific concentration, as therapeutic supplement in patients having specific insistion, as therapeutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for therapy. The present and skeletal muscle disorders an oligomer used in the screening of the hGDMLP-1 sequence in the exemplification of the present
                                                                                                                                                                                                                                                                                                                                       N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO

                                                                                                                                                                                   The present invention describes a human genome-derived myosin-like protein 1 (hGDMLP-1). The protein and polynucleotide sequences of hGDMLP-1 can be used in gene therapy and vaccine production. The hGDMLP-1 nucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 nucleic acids in samples, as amplification or be used intial substrates for the recombinant engineering of hGDMLP-1 protein variants having desired phenotypic improvements, and for expressing the proteins. The hGDMLP-1 proteins or polypeptides may be used as immunogens to raise antibodies that specifically recognise concentration and/or amount specifically of hGDMLP-1 proteins, as standards in assays used to determine the concentration and/or amount specifically of hGDMLP-proteins, as specific concentration, as therapeutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for diagnosing a disorder associated with the expression of hGDMLP-1, in callised to chromosome 22. The present sequence represents an oligomer used in the screening of the hGDMLP-1 sequence in the exemplification of the present
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              0;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO at ftp.wlpo.int/pub/published_pct_sequence.

The present invention describes a human genome-derived myosin-like protein 1 (hGDMLP-1). The protein and polynucleotide sequences of hGDMLP-1 can be used in gene therapy and vaccine production. The chGDMLP-1 mucleic acids can be used as probes to detect, characterise and quantify hGDMLP-1 nucleic acids in samples, as amplification consumerates, to provide initial substrates for the recombinant engineering of hGDMLP-1 protein variants having desired phenotypic improvements, and for expressing the proteins. The hGDMLP-1 proteins or polypeptides may be used as immunogens to raise antibodies that specifically recognise hGDMLP-1 proteins as standards in assays used to determine the concentration and/or amount specifically. Proteins as specific concentration and/or amount specifically proteins, as specific concentration, as therapeutic supplement in patients having specific deficiency in hGDMLP-1 production, and in vaccines or for replacement therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for therapy. The polynucleotide sequences encoding hGDMLP-1 may be used for theorem as alsorder associated with the expression of hGDMLP-1, in particular heart and skeletal muscle disorders of hGDMLP-1 is localised to chromosome 22. The present sequence represents an oligomer used in the serreening of the hGDMLP-1 sequence in the exemplification of the present
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          N.B. The sequence data for this patent did not form part of the printed specification, but was obtained in electronic format directly from WIPO at ftp.wipo.int/pub/published_pct_sequence.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Human; hammerhead ribozyme; cytostatic; antitumour; antidiabetic; cybthalmological; antiarthritic; antipsoriatic; virucide; osteopathic; vulnerary; cancer; lymphoma; Eving's sarcoma; melanoma; psoriasis; tumour angiogenesis; diabetic retinopath; macular degeneration; neovascular glaucoma; myopic degeneration; arthritis; verruca vulgaris;

The invention relates to a nucleic acid molecule (1) which down regulates expression of an Ets-related gene (ERG). (I) is useful for treating conditions selected from cancer. Jymphoma, Ewing's sarcona, melanoma, tumour angiogenesis, diabetic retinopathy, macular degeneration, unclaimed tumour angiogenesis, diabetic retinopathy, macular degeneration, verruca tumour angiogenesis, diabetic retinopathy, macular degeneration, verruca vulgaris, angiofibroma of tubercous sclerosis, port-wine stains, Sturge (Weber syndrome, Nippel-Trenaunay-Weber syndrome, Osler-Weber-rendu (Syndrome, leukaemia, osteoporosis and wound healing. (I) is useful for creating a patient having a condition associated with the level of ERG, by contacting cells of the patient with (I) under conditions suitable for the treatment. Leukaemia or tumour angiogenesis is treated by administering (I) to the patient in a columction with one or more of other therapies such as radiation or compunction with one or more of other therapies such as radiation or compunction with one or more of other therapies such as radiation or compunction with one or more of other therapies such as radiation or compunction with one or more of other therapies such as radiation or compunction with one or more of other therapies such as radiation or calion such as Mg2+. (I) is useful for reducing ERG activity in a cell, by contacting the cell with (I). (I) is useful for cleaving RNA of ERG such such as made of ERG RNA in a cell. (I) is useful for specifically the examine genetic drift and mutations within diseased cells or to detect the presence of ERG RNA in a cell. (I) is useful for specifically the ERG such and C targeting genes that share homology with ERG gene or ERG fusion genes. ABK17354-ABK22719 represent nucleic acids, including antisense and compared to the invention swich as minerations which regulate expression of ERG and related PCR primers of the invention

Novel polynucleotide which down regulates expression of Ets-related gene, useful for treating cancer, diabetic retinopathy, macular degeneration, arthritis, psoriasis, verruca vulgaris and Sturge Weber syndrome

Claim 4; Page 106; 149pp; English.

The invention relates to a nucleic acid molecule (I) which down regulates expression of an Ets-related gene (ERG). (I) is useful for treating conditions selected from cancer, lymphoma, Ewing's sarcoma, melanoma, tumour angiogenesis, diabetic retinopathy, macular degeneration, tenwascular glaucoma, myopic degeneration, arthritis, psoriasis, verruca vulgaris, angiofibroma of tubercus sclerosis, port-wine stains, Sturge Weber syndrome, Nippel-Trenaunay-Weber syndrome, Oslew-Weber-rendu cyndrome, leukaemia, osteoporosis and wound healing. (I) is useful for treating a patient having a condition associated with the level of ERG, by contacting cells of the patient with (I) under conditions suitable for the treatment. Leukaemia or tumour conditions suitable for the treatment. Leukaemia or tumour conjunction with one or more of other therapies such as radiation or conjunction with one or more of other therapies such as radiation or conjunction with one or more of other therapies such as radiation or cell, by contacting (I) is useful for reducing ERG activity in a cell, by contacting (I) is useful for diagnostic tool to diseases related to the expression of ERG, and as diagnostic tool to camine genetic drift and mutarions within diseased cells or to detect the presence of ERG RNA in a cell. (I) is useful for specifically cargeting genes that share homology with ERG gene or ERG fusion genes.

ABRIJSTA ABRIZITY represent moleic acids, including antiense and contacting the cell with the cell with ERG gene or ERG fusion genes. ABKİ7354-ABK22719 represent nucleic acids, including antisense and enzymatic nucleic acid molecules which regulate expression of ERG, and related PCR primers of the invention.

Novel polynucleotide which down regulates expression of Ets-related gene, useful for treating cancer, diabetic retinopathy, macular degeneration, arthritis, psoriasis, verruca vulgaris and Sturge Weber syndrome

Claim 4; Page 120; 149pp; English.

The invention relates to a nucleic acid molecule (I) which down regulates expression of an Ets-related gene (ERG). (I) is useful for treating conditions selected from cancer, lymphoma, Ewing's sarcoma, melanoma, tumour angiogenesis, diabetic retinopathy, macular degeneration, melanoma, tumour angiogenesis, diabetic retinopathy, macular degeneration, verruca vulgaris, angiofibroma of tuberous sclerosis, port-wine stains, Sturge weber syndrome, Rippel-Trenaunay-Weber syndrome, Osteoporosis and wound healing. (I) is useful for treating a patient having a condition associated with the level of ERG, by contacting cells of the patient with (I) under conditions suitable for the treatment. The method comprises the use of one or more therapies the treatment. The method comprises the use of one or more therapies conditions suitable for the treatment. Leukaemia or tumour angiogenesis is treated by administering (I) to the patient in conjunction with one or more of other therapies such as radiation or chemotherapy treatment. (I) is useful for reducing ERG activity in a cell, by contacting the cell with (I). (I) is useful for classing and diseases related to the expression of ERG, and as diagnostic tool to examine genetic drift and mutations within diseased cells or to detect the presence of ERG RAM in a cell. (I) is useful for specifically the contacting the cell with diseased cells or to detect the presence of ERG RAM in a cell. (I) is useful for specifically the contacting the cell (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting the cell. (I) is useful for specifically the contacting targeting genes that share homology with ERG gene or ERG fiscally ABK77354-ABK22719 represent nucleic acids, including antisense and enzymatic nucleic acid molecules which regulate expression of ERG, and related PCR primers of the invention.

creating plants with desired phenotypes, e.g. stress tolerance, roved nutritional value, herbicide or disease resistance, or ified oil production New oligonucleotides with modified nuclease-resistant termini, modified

Claim 7; Page 148; 220pp; English.

generic sequence, which comprises a single-stranded oligonuclectide
having a DNA domain. The DNA domain has at least one mismatch with
cepect to the genetic sequence to be altered and further comprises
chemical modifications of the oligonucleotide. The chemical modifications
consist of o-methyl modification, an LNA modification, two or more
phosphorothioate linkages on a terminus, or a combination of any two or
more of these modifications. The oligonucleotides are useful for
directing repair or alteration of plant genetic information. The
oligonucleotides are particularly useful for creating plants with desired
coligonucleotides are particularly useful for creating plants with desired
nutritional value (e.g. altering amino acid content of plants or
conferring amino acid over production), herbicide resistance (e.g.
glyphosate resistance, imidazolinone and sulphonylurea herbicide
resistance, porphyric herbicide resistance or triazine resistance), of. The invention relates to an oligonucleotide for targeted alteration

              (e.g. increased starch or production of waxy starch), altered floral morphology (e.g. male-sterile plants) or modified fatty acid content (e.g. reduced palmitate, increased stearate or reduced linolenic acid). The oligomuclectides are also useful for producing albino mutants for the analysis of photosynthetic processes. This sequence represents a genome altering oligomuclectide of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Chromosomal genomic alteration; genome altering oligonucleotide; PCR; ss; o-methyl modification; LNA modification; phosphorothicate linkage; DNA repair; DNA alteration; environmental tolerance; hygromycin-B; abiotic stress tolerance; improved nutritional value; hygromycin, primer; amino acid over production; herbicide resistance; glyphosate resistance; imidazolinone herbicide resistance; sulphonylurea herbicide resistance; prophyric herbicide resistance; triazine resistance; disease resistance; modified oil production; modified starch production; waxy starch; altered floral morphology; male-sterile plant; albino mutant; modified fatty acid content; reduced palmitate production; albino plant; increased stearate production; reduced linolenic acid production;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             The invention relates to an oligonuclectide for targeted alteration of a genetic sequence, which comprises a single-stranded oligonuclectide having a DNA domain. The DNA domain has at least one mismatch with respect to the genetic sequence to be altered and further comprises chemical modifications of the oligonuclectide. The chemical modifications
disease resistance, modified oil production, modified starch production
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           oligonucleotides with modified nuclease-resistant termini, useful
                                                                                                                                                                                                                                           Gaps

consist of o-methyl modification, an LNA modification, two or more phosphorothicate linkages on a terminus, or a combination of any two or more of these modifications. The oligonucleotides are useful for directing repair or alteration of plant genetic information. The oligonucleotides are useful for creating plants with desired oligonucleotides are particularly useful for creating plants with desired phenotypes, e.g. environmental or abiotic stress tolerance, improved nutritional value (e.g. altering amino acid over production), herbicide resistance (e.g. conferring amino acid over production), herbicide resistance (e.g. glyphosate resistance, imidazolinone and sulphorylurae herbicide creastance, porphyric herbicide resistance or triazine resistance), disease resistance modified oil production, modified starch production (e.g. increased starch or production) waxy starch), altered floral morphology (e.g. male-sterile plants) or modified fatty acid content (e.g. reduced palmitate, increased stearate or reduced linolenic acid). The oligonucleotides are also useful for producing albino mutants for the analysis of photosynthetic processes. This sequence represents a genome altering oligonucleotide of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       o-methyl modification; LNA modification; phosphorothicate linkage;

genetic sequence, which comprises a single-stranded oligonuclectide having a DNA domain. The DNA domain has at least one mismatch with having a DNA domain. The DNA domain has at least one mismatch with craspect to the genetic sequence to be altered and further comprises chemical modifications of the oligonucleotide. The chemical modifications consist of o-methyl modification, an LNA modification, two or more phosphorothicate linkages on a terminus, or a combination of any two or more of these modifications. The oligonucleotides are useful for
                                                                                                                                                                                                                                                                                                                                                                                 directing repair or alteration of plant genetic information. The oligomucleotides are particularly useful for creating plants with desired phenotypes, e.g. environmental or abiotic stress tolerance, improved mutritional value (e.g. altering amino acid content of plants or conferring amino acid over production), herbicide resistance (e.g. glyphosate resistence, imidazolinone and sulphonylurea herbicide resistance resistance, porphyric herbicide resistance or triazine resistance), disease resistance, modified oil production, modified starch production (e.g. increased starch or production of waxy starch) altered floral
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   morphology (e.g. male-sterile plants) or modified fatty acid content (e.g. reduced palmitate, increased stearate or reduced linolenic acid). The oligonucleotides are also useful for producing albino mutants for the analysis of photosynthetic processes. This sequence represents a genome altering oligonucleotide of the invention.
                                                                                                                                                              of a

New oligonucleotides with modified nuclease-resistant termini, useful for creating plants with desired phenotypes, e.g. stress tolerance, improved nutritional value, herbicide or disease resistance, or modified oil production -

Claim 7; Page 162; 220pp; English.

genetic sequence, which comprises a single-stranded oligonucleotide having a DNA domain. The DNA domain has at least one mismatch with respect to the genetic sequence to be altered and further comprises chemical modifications of the oligonucleotide. The chemical modifications of the oligonucleotide. The chemical modifications of the oligonucleotide are useful for phosphorothhoate linkages on a terminus, or a combination of any two or more of these modifications. The oligonucleotides are useful for directing repair or alteration of plant genetic information. The oligonucleotides are particularly useful for creating plants with desired phototypes, e.g. environmental or abiotic stress tolerance, improved nutritional value (e.g. altering amino acid cover production), herbicide resistance (e.g. glyphosate resistance, indazolinone and sulphonylurea herbicide resistance), disease resistance, modified oil production, modified starch production (e.g. increased starch or production of waxy starch), altered floral morphology (e.g. male-sterile plants) or modified fatty acid content (e.g. reduced palmitate, increased stearate or reduced linolenic acid). The oligonuclectides are also useful for producing albino mutants for the analysis of photosynthetic processes. This sequence represents a genome of a invention relates to an oligonucleotide for targeted alteration altering oligonucleotide of the invention.

                                                                                                                                                                      The present invention relates to the isolation of human and mouse checkpoint (chk1) proteins and the nucleic acid sequences encoding them. Human chk1 (hchk1) maps to chromsome ilg4. Chk1 is involved in cellular responses to DNA damage, in the cell cycle checkpoint pathway. The protein is useful for generating specific antibodies and for inhibiting the growth of cells. The muleotide sequence encoding the protein may be used as a probe for a portion of the chromosome associated with tumours and other malignancies, as well as growth and/or used to amplify cDNA encoding the human chk1 protein from a human B-cell cDNA library,

The invention relates to a novel isolated 17 mer nucleic acid sequence, given in the specification, a sequence containing at least 15 consecutive nucleotides from the 17 mer sequence, a sequence with, after content of a light at least 80 % identity to the 17 mer sequence, a sequence with, after optimal alignment, at least 80 % identity to the 17 mer sequence. C sequence that hybridizes to them under highly stringent conditions, or the complement of any of them, or the corresponding RNA. The novel isolated nucleic acids of the invention are useful as probes and primers for detecting, identifying, quantifying and/or amplifying a nucleic acid, ce.g. as one component of a gene chip, in vitro as (anti)sense reagents, and for production of recombinant polypeptides. Any of the nucleic acids, polypeptides, vectors containing the nucleic acids, cells containing the nucleic acids, colls containing the nucleic acids, colls exercised by development of tumours or cell diseases that are characterised by development of tumours or cell degeneration, specifically cancer but also Alzheimer's disease and softing patient samples is useful for diagnosis and/or prognosis of these containing the polypeptides can also be used to generate antibodies, and the molypeptides can also be used to generate antibodies, and the molypeptides can also be used to generate antibodies.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Cytostatic; virucide; neuroprotective; nootropic; neuroleptic; gene chip; antisense; sense; tumour; cell degeneration; cancer; Alzheimer's disease; schizophrenia; protein chip; gene therapy; tumour suppression; human fukutin; ds.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             both the polypeptide and antibodies are useful as components of protein chips. The nucleic acid sequences of the invention can be used in gene therapy. This polynucleotide sequence represents a tumour suppression related human fukutin oligonucleotide of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The invention relates to a novel isolated 17 mer nucleic acid sequence, given in the specification, a sequence containing at least 15
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 0
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Tumour suppression related human fukutin oligo SEQ ID No 837.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Length 17;

consecutive nucleotides from the 17 mer sequence, a sequence with, after optimal alignment, at least 80 % identity to the 17 mer sequence, a sequence that hybridizes to them under highly stringent conditions, or the complement of any of them, or the corresponding RNA. The novel isolated nucleic acids of the invention are useful as probes and primers for detecting, identifying quantifying and/or amplifying a nucleic acid, e.g. as one component of a gene chip, in vitro as (anti) sense reagents, and for production of recombinant polypeptides. Any of the nucleic acids, polypeptides, vectors containing the nucleic acids, and for production of recombinant polypeptides. Any of the nucleic acids, polypeptides, vectors containing the polypeptides are useful for preparation of pharmaceuticals for prevention and/or treatment of viral diseases that are characterised by development of tumours or cell diseases that are characterised by development of tumours or cell degeneration, specifically cancer but also Alzhaimer's disease and expirate tamples is useful for diagnosis and/or prognosis of these diseases. The polypeptides can also be used to generate antibodies, and both the polypeptide and antibodies are useful as components of protein the polypeptide and antibodies are useful as components of protein therapy. This polymucleotide sequence represents a tumour suppression related human fukutin oligonucleotide of the invention. \$

New isolated nucleic acid, useful for treating viral diseases associated with tumors and cell degeneration, also related polypeptides, antibodies and transfected cells

Disclosure; Page 178; 720pp; French.

The invention relates to a novel isolated 17 mer nucleic acid sequence, given in the specification, a sequence containing at least 15 consecutive nucleotides from the 17 mer sequence, a sequence with, after optimal alignment, at least 80 % identity to the 17 mer sequence, a

sequence that hybridizes to them under highly stringent conditions, or the complement of any of them, or the corresponding RNA. The novel isolated nucleic acids of the invention are useful as probes and primers for detecting, identifying, quantifying and/or amplifying a nucleic acid, e.g. as one component of a gene chip, in vitro as (anti)sense reagents, and for production of recombinant polypeptides. Any of the nucleic acids, polypeptides, vectors containing the nucleic acids, polypeptides, vectors containing the nucleic acids, cells containing the nucleic acids, cells containing the preparation of plaramaceuticals for prevention and/or treatment of viral diseases that are characterised by development of tumours or cell diseases that are characterised by development of tumours or cell diseases that annuales is useful for diagnosis and/or prognosis of these diseases. The polypeptides can also be used to generate antibodises, and both the polypeptide and antibodies are useful as components of protein chips. The nucleic acid sequences of the invention can be used in gene therapy. This polynucleotide sequence represents a tumour suppression related human fukutin oligonucleotide of the invention.

New isolated nucleic acid, useful for treating viral diseases associated with tumors and cell degeneration, also related polypeptides, antibodies and transfected cells

Disclosure; Page 360; 720pp; French.

The invention relates to a novel isolated 17 mer nucleic acid sequence, given in the specification, a sequence containing at least 15 consecutive nucleotides from the 17 mer sequence, a sequence with, after optimal alignment, at least 80 % identity to the 17 mer sequence, a sequence that hybridizes to them under highly stringent conditions, or the complement of any of them, or the corresponding RNA. The novel

for detecting, identifying, quantifying and/or amplifying a nucleic acid, e.g. as one component of a gene chip, in vitro as (anti)sense reagents, and for production of recombinant polypeptides. Any of the nucleic acids, polypeptides, vectors containing the nucleic acids, cells containing the vector or antibodies directed against the polypeptides are useful for diseases that are characterised by development of tumours or cell degeneration, specifically cancer but also Alzheiner's disease and schizophrenia. Analysis of the expression of the 17 mer nucleic acids in patient samples is useful for diagnosis and/or prognosis of these diseases. The polypeptides can also be used to generate antibodies, and both the polypeptide and antibodies are useful as components of protein chips. The nucleic acid sequences of the invention can be used in gene nucleic acids of the invention are useful as probes and primers therapy. This polynucleotide sequence represents a tumour suppression related human fukutin oligonucleotide of the invention.

regulates expression of a sequence encoding a subunit of nuclear factor kappa B (NFKB), where [1] is an inoxyme, zinzyme, G-cleaver or amberzyme configuration. The enzymatic nucleic acid molecule is adapted to treat cancer and is useful for down-regulating REL-A activity in a cell, for treating a patient having a condition associated with the level of REL-A. [1] is useful for cleaving RNA comprising a sequence of REL-A gene, in the presence of a divalent cation, especially MG-2+. The enzymatic and ntisense nucleic acid molecules are useful for treating breast, lung, prostate, colorectal, brain, oesophageal, stoomach, bladder, pancreatic, cervical, head and neck, ovarian cancer, melanoma, lymphoma, glioma or multidrug resistant cancer. The method involves use of other drug theraphes such as monoclonal antibodies, REL-A-specific inhibitors or chemotherapy including paclitaxel, docetaxel, cisplatin, methotrexate, gemitiable of axorubin, fluorouracil carboplatin, edatrexate, concluding paclitaxel, docetaxel, cisplatin, methotrexate, cold molecules are also useful for treating inflammatory disease such as rheumatoid arthritis, restenosis, asthma, Crohn's disease, diabetes, cobesity, autoimmune disease, lupus, multiple scleroals, transplant/graft rejection, gene therapy applications, isobaemia/treperfusion injury (central nervous system (CNS) and myocardial), glomerulonephritis, septement of a nowell sease or inflammatory of a nowel is sease or inflammatory of a nowel
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    .

The invention describes an enzymatic nucleic acid molecule (I) which down regulates expression of a sequence encoding a subunit of nuclear factor regulates expression of a sequence encoding a subunit of nuclear factor (2 kappa B (NRKB), where (I) is an inozyme, G-cleaver or amberzyme configuration. The enzymatic nucleic acid molecule is adapted to treat cancer and is useful for down-regulating REL-A activity in a cell, for treating a patient having a condition associated with the level of REL-A. Gene, in the presence of a divalent cation, especially MG^2+. The enzymatic and antisense nucleic acid molecules are useful for treating breast, lung, prostate, colorectal, brain, oesophageal, stomach, bladder, pancreatic, cervical, head and neck, ovarian cancer, melanoma, lymphoma, glioma or multidrug resistant cancer. The method involves use of other drug cherotherapy including paclitaxel, docetaxel, cisplatin, methotrexate, cyclophosphamide, doxorubin, fluorouracil carboplatin, edatrexate, cyclophosphamide, doxorubin, fluorouracil carboplatin, edatrexate, cyclophosphamide, doxorubin, fluorouracil carboplatin, edatrexate, contendation arthritis, restenoosis, asthma, Crohn's disease such as caid molecules are also useful for treating inflammatory disease such as chemmatoid arthritis, restenoosis, asthma, Crohn's disease, diabetes, celectral nervous system (CNS) and myocardial), glomerulonephritis, centering inflammatory bowel disease or infection. This sequence represents the substrate of a novel
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              oervical cancer; had and neck cancer; ovarian cancer; melanoma; lymphoma; glioma; multidrug resistant cancer; REL-A-specific inhibitor; hemotherapy; paclitaxel; docetaxel; otsplatin; methotrexate; cyclophosphanide; doxorubin; fluorouracil carboplatin; edatrexate; gemcitabine; radiation therapy; inflammatory disease; asthma; diabetes; froumation arthritis; restenosis; Grohn's disease; obesity; ischemia; gene therapy; autoimmune disease; lupus; multiple sclerosis; sepsis; transplant/graft rejection; reperfusion injury; glomerulonephritis; allergic airway inflammation; inflammatory bowel disease; infection;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Enzymatic nucleic acid; nuclear factor kappa B; NFKB; inozyme; zinzyme; G-cleaver; amberzyme; cancer; REL-A activity; breast cancer; human; lung cancer; prostate cancer; colorectal cancer; brain cancer; oesophageal cancer; stomach cancer; bladder cancer; pancreatic cancer;
                                                                                                                                                                                                                                                                                                          Novel enzymatic nucleic acid molecules which down regulates expression of a sequence encoding a subunit of nuclear factor kappa B useful for treating cancer, inflammatory disorders and autoimmune diseases

The invention describes an enzymatic nucleic acid molecule (I) which down kappa B (NFKB), where (I) is an inozyme, Zinzwe, G-cleaver or amberzyme configuration. The enzymatic nucleic acid molecule is adapted to treat configuration. The enzymatic nucleic acid molecule is adapted to treat cancer and is useful for down-regulating REL-A activity in a cell, for treating a patient having a condition associated with the level of REL-A. (I) is useful for cleaving RNA comprising a sequence of REL-A gene, in the presence of a divalent cation, especially Mg^2+. The enzymatic and antisense nucleic acid molecules are useful for treating breast, lung, prostate, colorectal, brain, oesophageal, stomach, bladder, pancreatic, cervical, head and neck ovarian cancer, melanowa, lymphoma, glioma or multidrug resistant cancer. The method involves use of other drug cherapies such as monoclonal antibodies, REL-A-specific inhibitors or chemotherapy including paclicaxel, docetaxel, cisplatin, methotrexate, cyclophosphamide, docorubin, fluorouracil carboplatin, methotrexate, gencitabine or radiation therapy. The enzymatic and antisease such as including paclicaxel, acidentical architecture are also useful for treating inflammatory disease such as rejection, gene therapy applications, multiple sclerosis, transplant/graft (contral) contral contral contral cation, disease, lupus, multiple sclerosis, transplant/graft (contral) contral cation, general contral cations, including molecules are also weeful for treating inflammatory disease such as rejection, gene therapy applications, multiple sclerosis, transplant/graft (contral) contral cation, general contral cations, including cations, and contral cations, including cations, and contral cations, and cont
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Novel enzymatic nucleic acid molecules which down regulates expression of a sequence encoding a subunit of nuclear factor kappa B useful for treating cancer, inflammatory disorders and autoimmune diseases
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       (central nervous system (CNS) and myocardial), glomerulonephritis, sepsis, allergic airway inflammation, inflammatory bowel disease or infection. This sequence represents the substrate of a novel

Novel enzymatic nucleic acid molecules which down regulates expression of a seguence encoding a subunit of nuclear factor kappa B useful for treating cancer, inflammatory disorders and autoimmune diseases

3; Page 38; 72pp; English

The invention describes an enzymatic nucleic acid molecule (I) which down regulates expression of a sequence encoding a subunit of nuclear factor regulates expression of a sequence encoding a subunit of nuclear or amberzyme configuration. The enzymatic nucleic acid molecule is adapted to treat cancer and is useful for down-regulating RL-A activity in a cell, for treating a patient having a condition associated with the level of REL-A. (I) is useful for cleaving RNA comprising a sequence of REL-A gane, in the presence of a divalent cation, especially MG^2+. The enzymatic and antisense nucleic acid molecules are useful for treating breast, lung, prostate, colorectal, brain, oesophageal, stomach, bladder, pancreatic, cervical, head and neck, ovarian cancer, melanoma, lymphoma, glioma or multidrug resistant cancer. The method involves use of other drug cherrappy including paclitaxel, doctaxel, cisplatin, methotrexate, cyclophosphamide, doxorubin, fluorouracil carboplatin, edatrexate, cyclophosphamide, doxorubin, fluorouracil carboplatin, edatrexate, cyclophosphamide, doxorubin, fluorouracil carboplatin, edatrexate, cyclophosphamide, and outleting or radiation therapy. The enzymatic and antisense nucleic acid molecules are also useful for treating inflammatory disease such as confident arbitis, restenoosis, asthma crossis, transplant/graft crefetchin, gene therapy applications, ischemialrepense, diabetes, conferential method in the colors of conference of colors. bowel disease or (central nervous system (CNS) and myocardial), glomerulonephritis, sepsis, allergic airway inflammation, inflammatory bowel disease o infection. This sequence represents the substrate of a novel sequence represents the substrate of a novel enzymatic nucleic acid molecule.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 The invention describes an anti-Chkl antibody capable of specifically binding to an antigenic determinant on the proteins encoded by a sequence comprising 476 (3 sequences), 479, 496 or 513 amino acids. A new method is used to produce the antibody, which is useful for detecting a Chkl protein that is associated with a tumour. This sequence represents a primer used in mapping of human checkpoint

The present invention relates to a novel method for the isolation of endothelial cells (ECs), and the identification of genes expressed in normal and tumnour ECs. Tumour endothelial marker (TEM), normal endothelial marker (TEM), normal and tumnour ECs. The human EC marker proteins and the joblymucleotide sequences encoding them are useful for detecting, diagnosing or treating tumnours as well as polycystic kidney disease, diabetic retinopathy, rheumatoid arthritis, and psoriasis. They are also useful for inhibiting neoangiogenesis or tumour angiogenesis, for inducing an immune response to tumour endothelial cells in a patient, or for identifying candidate drugs for treating tumours. ABX72067-ABX72116 represent human TEM DNA tags.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Gaps
               pan-endothelial marker; polycystic kidney disease; psoriasis; dabetic retinopathy; rheumatoid arthritis; tumour angiogenesis; necangiogenesis; immune response; cytostatic; antidiabetic; ophthalmological; antirheumatic; antiarthritic; antigoriatic; ds.
                                                                                                                                                                                                                                                                                                                                                                                                                New purified human transmembrane protein, designated as tumour andothelial marker (TEM) 3. useful for detecting, diagnosing or treating tumours, polycystic aidney disease, diabetic retinopathy, rheumatoid arthritis or psoriasis
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Human; ribozyme; short interfering RNA; siRNA; HER2; K-Ras; enzymatic nucleic acid; H-Ras; N-Ras; HIV; cytostatic; anti-HIV; anti-rheumatic; cancer; AIDS; ss.

The invention relates to a novel short interfering RNA (siRNA) nucleic acid molecule, that modulates expression of a nucleic acid molecule encoding HER2, K-Ras, H-Ras, N-Ras, human immunodeficiency virus (HIV) or a component of HIV. The nucleic acid molecule of the invention has cytostatic, anti-HIV, and anti-rheumatic activity. The nucleic acid molecules are useful for reducing HER2, K-Ras, H-Ras, and HIV activity in a cell. The nucleic acids are also useful for treating breast, ovarian, colorectal, lung, prostate, bladder, or panoreatic cancer, and HIV infection, and AIDS. The sequences shown in ABZ56889 - ABZ66516, ABZ66530 - ABZ66521, ABZ66530 - ABZ66515, Epresent substrate/target sequences for the human ribozymes of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Gaps
                                                                                                                                                                                                                      treating cancer, modulates the expression of a nucleic acid encoding HER2, K-Ras, H-Ras, N-Ras, and human deficiency virus sequences
                                                                                                                                                                                                       Novel short interfering RNA and enzymatic nucleic acid useful for
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Human, ribozyme, short interfering RNA, siRNA, HER2, K-Ras, enzymatic nucleic acid, H-Ras, N-Ras, HIV, cytostatic, anti-HIV, anti-rheumatic, cancer, AIDS, ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          0;

The invention relates to a novel short interfering RNA (siRNA) nucleic acid molecule, that modulates expression of a nucleic acid molecule acid molecule, that modulates expression of a nucleic acid molecule encoding HER2, K-Ras, H-Ras, N-Ras, human immunodeficiency virus (HIV) or a component of HIV. The nucleic acid molecule of the invention has cytostatic, anti-HIV, and arti-rheumatic activity. The nucleic acid molecules are useful for reducing HER2, K-Ras, H-Ras, and HIV activity in a cell. The nucleic acids are also useful for treating breast, ovarian, colorectal, lung, prostate, bladder, or pancreatic cancer, and HIV infection, and AIDS. The sequences shown in ABZ55889 - ABZ65216, ABZ6520 - ABZ65231, ABZ6520 - ABZ652216, ABZ6531, ABZ6520 - ABZ65231, ABZ6530 - ABZ65316 resent substrate/target sequences for the human ribozymes of the invention.

                                                                                                                                                                                                                                                                                                                                                                                                                       ð
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ö
                                                                                                                                                                                               The invention relates to a novel short interfering RNA (siRNA) nucleic acid molecule or an enzymatic nucleic acid molecule, that modulates expression of a nucleic acid molecule encoding HRS2, K-Ras, H-Ras, M-Ras, human immunodeficiency virus (HIV) or a component of HIV. The nucleic acid molecule of the invention has cytostatic, anti-HIV, and anti-rheumatic activity. The nucleic acid molecules are useful for reducing HBR2, K-Ras, H-Ras, and HIV activity in a cell. The nucleic acids are also useful for treating breast, ovarian, colorectal, lung, prostate, bladder, or pancreatic cancer, and HIV infection, and AIDS. The sequences shown in ABZ56989 - ABZ66216, ABZ64514 - ABZ65531, ABZ66520 - ABZ66520 - ABZ665216, ABZ66530 - ABZ665216, ABZ66530 - ABZ66510 - ABZ66531,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The invention relates to a novel short interfering RNA (siRNA) nucleic acid molecule, that modulates expression of a nucleic acid molecule encoding HER2, K-Ras, H-Ras, N-Ras,

The present invention describes a method for constructing a CDNA tag for identifying an expressed gene. The method comprises: (a) preparation of complementary decxyribonuclera caid, (b) producing cDNA fragment by cleavage with II type restriction caid, (b) producing cDNA fragment by cleavage with II type restriction enzyme; (c) obtaining a linker X-CDNA fragment ligated material; (d) amplification of the linker X-CDNA taglinker Y ligated material; and (e) cleaving the amplification product. The method can be used for the construction of cDNA tags for identifying expressed genes, which is applicable in gene expression analysis, disease diagnosis and identifying target for gene therapy, including the clarification of difference in function or morphology of cells under be specifically expressed, with responducibility and accuracy in the detection of genes. The present sequence represents an expressed gene identification (EGI) cDNA tag related oligonucleotide which is used in
                                                                                                                                                                                                                                                                                                                                                                                                                      identification (EGI) cDNA tag related an example from the present invention.

Identifying pain-regulating compounds, useful for treating chronic pain and for diagnosis, by measuring binding of compounds to specific peptides and proteins -

Example 1; Page 62; 213pp; German.

The invention relates to identifying pain-regulating substances (A) comprises (1) incubating a test substance with a cell (or preparation from it) that has synthesised a peptide or protein (B) and (ii) measuring either binding of the test substance to (B) or some functional parameter that is altered by this binding. The method is useful for identifying pain-regulating substances (A) with analgesic activity, (A) along with nucleic acid (ABL88411-ABL88441) that encode proteins (B) ABB85005-ABB85037) that interact with (A); (B); vectors containing the nucleic acid; antibodies against (B); cells that express (B) and agents hat bind to (B), are all useful for treating pain, particularly chronic pain, including use in gene therapy. The same materials can also be used for diagnosis, e.g. of neurological and neurodegenerative diseases. The present sequence is that of a PCR primer, used in examples of the nvention

The present invention relates to retinoid (e.g., retinoic acid (RA), vitamin A) metabolising proteins and nucleic acid sequences encoding them. RA metabolising proteins contain a haeme-binding motif which is characteristic of the group of proteins known as cytochrome P450s. The sequences of the invention are useful in retinoid metabolism and in producing retinoic acid metabolising cytochrome P450s. They are particularly useful as targets for the treatment of certain cancers such as prostate cancer. The invention also relates to a method of screening drugs for their effect on activity of RA inducible proteins. The present DNA sequence is poly(T) PCR primer which is used for
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             isolating retinoid regulating genes by differential display of mRNAs.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Human ICAM hammerhead ribozyme target sequence (nt. position 2909)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Bnzymatic nucleic acid; ribozyme; trans cleavage; inhibition; gene expression; downregulation; interleukin-5; IL-5; ICAM-1; intercellular adhesion molecule; rel A; tumour necrosis factor; TNF-alpha; respiratory syncytial virus; RSV; bcr-abl; oncogene; translocation; chronic myelogenous leukaemia; CML; cancer; Philadelphia chromosome; inflammation; autoimmune disease; atherosclerosis; myocardial inflarction; stroke; restenosis; transplant rejection; rheumatoid arthritis; psoriasis; human immunodeficiency virus; acquired immune deficiency syndrome; AIDS; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  ó
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present invention describes a method for detecting single nucleotide polymorphisms (SNPs). Also described is an oligonucleotide used in the detection of an SNP, prepared by binding an oligonucleotide having a complementary sequence or those devoid of up to several bases with 1 or more organic group(s) to be tested by light irradiation of a specific oligonucleotide to be tested. The method is used for detecting SNPs. The present sequence represents a light responsive oligonucleotide which

The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves ICAM-1 mRNA at the nucleotide base position indicated in the DE line.

Regions of the mRNA that do not form secondary folding structures and that contain potential harmerhead and hairpin ribozyme cleavage sites were identified by computer analysis.

C Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant rejection and alleviating symptoms in patients with rheumatoid arthritis, asthma and other inflammatory disorders.

(Updated on 25-MAR-2003 to correct PI field.)

ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant rejection and alleviating symptoms in patients with rheumatoid arthritis, asthma and other inflammatory disorders. The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves ICAM-1 mRNA at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin (Updated on 25-MAR-2003 to correct PI field.)

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation

Example 8; Page 88; 201pp; English

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated coll proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, blood vessels or any other hyperplasia.

oligonuclectide which binds in parallel and antiparallel orientation, respectively, for targetting sequences on alternate strands of DHNA to control gene expression. A triple-helix comprising a double helical nucleic acid (DHNA) and an

Example 6; Fig 20A; 108pp; English.

therapeutic purposes. The oligomucleotides can be selected to specifically bind to pathogenic double-stranded DNA including specific sequences required by pathogenic bacteria or viruses for replication or virulence, reducing their pathogenic harmonic pathogenic, Alternatively, the oligomucleotide can be chosen to target a unique sequence of the pathogen which is not found in the genome of pathogen's host. The The present invention relates to methods and oligonucleotides for forming a triple-helix comprising a double helical nucleic acid comprising first and second substantially complementary strands, and an oligonucleotide bound to a purine-rich target sequence within the parallel and antiparallel orientation, respectively, to target sequences on alternate strands of the double helical nucleic acid. Where the oligonucleotide binds in a sequence on alternate strands of the double helical nucleic acid. The method has therapeutic applications, where gene expression is controlled by selective triple-helix formation within expression regulatory sequences of a target gene. The oligonucleotides can be used to form triple-helices, and are useful to detect the presence or absence of specific sequences within genomic DNA for diagnostic and

A triple-helix comprising a double helical nucleic acid (DHNA) and an oligonuclectide which binds in parallel and antiparallel orientation, respectively, for targetting sequences on alternate strands of DHNA to control gene expression

Example 7; Fig 24A; 108pp; English.

The present invention relates to methods and oligonucleotides for forming a triple-helix comprising a double helical nucleic acid comprising first and second substantially complementary strands, and an oligonucleotide bound to a purine-rich target sequence within the double helical nucleic acid, where the oligonucleotide binds in a parallel and antiparallel orientation, respectively, to target sequences on alternate strands of the double helical nucleic acid. The method has therapeutic applications, where gene expression is controlled by selective triple-helix formation within expression is regulatory sequences of a target gene. The oligonucleotides can be used to form triple-helices, and are useful to detect the presence or used to form triple-helices, within genomic DNA for diagnostic and therapeutic purposes. The oligonucleotides can be selected to specifically bind to pathogenic double-stranded DNA including specific sequences required by pathogenic bacteria or viruses for replication or virulence, reducing their pathogenicity. Alternatively, the

oligonucleotide can be chosen to target a unique sequence of the pathogen which is not found in the genome of pathogen's host. The oligonucleotides can be used in cancer treatment by way of triphe-helix suppression of specific oncogenes including those of endogenous or triple-helices with such therapeutic oligonucleotides are capable of forming triple-helices with such sequences in cancerous cells containing the activated oncogene, so preferentially killing or repressing the cancer causing cell. The present sequence represents an oligonucleotide used in the methods of the present invention.

Garner HR, Wren JD,

Identifying a candidate polymorphic repeat within a coding sequence, for understanding or treating genetic disease, comprises detecting tandem repeats in a target coding sequence and scoring the repeats for polymorphic probability -WPI; 2003-208818/20.

Fondon JW;

Minna JD,

Examples; Column 747; 588pp; English

The invention discloses a method for identifying a candidate polymorphic repeat within a coding sequence (expressed sequence tag, EST), which comprises detecting tandem repeats in a target coding sequence, scoring the repeats for polymorphic probability and generating a dataset correlating the repeats with polymorphic probability to identify a marker prediction of ubiquitous simple sequences, poMpous, and Rep-X) are useful for identifying and detecting candidate polymorphic repeats in human genes, which can be used to understand, treat or eliminate genetic diseases, predispositions or adverse drug-treatment reactions. The invention relates to sequences of at least two nucleotides of formula:

(X) m5. (alpha)n-beta-N3.; or (X) m5. (gamma)k-delta-N3.; where

X = a labelled compound and/or a nucleotide with voluntary sequence;

m = 0 or 1; alpha = thymine; n = natural number indicating the repetition of alpha; beta, delta = V or N; V = adenine, guanine or cytosine;

N = adenine, guanine, cytosine or thymine; gamma = thymine; gamma, in which thymine expressed by gamma is composed of 1/3 or less of adenine, guanine and/or cytosine. The new nucleotides are useful as primers for reproductive and highly efficient analysis of gene sequences.
              syndrome, Huntington's disease, fragile-X syndrome, Fredreich's ataxis, mytoonic dystrophy, hyperandrogenaemia, spinal and bulbar atrophy and spinocerebellar ataxia. The sequences presented in ABX79676-ABX80022 are the polymorphic repeats identified for a search of human BSTB.
diseases linked to nucleotide repeats are Machado-Joseph, Haw River

This sequence represents a primer of the invention. The invention relates to sequences of at least two nucleotides of formula:

(X)m5'. (alpha)n-beta-M3', or (X)m5'. (gamma)k-delta-M3', where

X = a labelled compound and/or a nucleotide with voluntary sequence;

m = 0 or 1; alpha = thymine; n = natural number indicating the repetition of alpha; beta, delta = V or N; V = adenine, gamma = thymine or cytosine;

N = adenine, guanine, cytosine or thymine; gamma = thymine;

k = natural number of 3 or over indicating the repetition of gamma, in which thymine expressed by gamma is composed of 1/3 or less of adenine, guanine and/or cytosine. The new nucleotides are useful as primers for reproductive and highly efficient analysis of gene sequences.
                                                                                                                                                         RT-PCR primer; DNA sequence determination; gene sequence analysis; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                          Peptides having at least two new nucleotides - useful as primers in
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Sequence 16 BP; 0 A; 1 C; 1 G; 14 T; 0 other;

Oligo-dT PCR primer #5 used to illustrate the method of the invention.

Sequential consensus region-directed amplification, gene expression, disease diagnosis; gene analysis; human; matrix metalloproteinase; PCR; primer; ss.

Unidentified

21-AUG-2001

```
The invention relates to a method of sequential consensus region-directed amplification for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples. The methods, kits and oligonucleotides are useful for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples e.g. for disease diagnosis and gene analysis. The present sequence is oligo dT PCR primer used to illustrate the method of the invention.
                                                                                                                                                                                                          Sequential consensus region-directed amplification for sorting mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples, useful for disease diagnosis and gene analysis -

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The invention relates to a method of sequential consensus region-directed amplification for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples. The methods, kits and oligonucleotides are useful for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples e.g. for disease diagnosis and gene analysis. The present sequence is oligo dT PCR primer used to illustrate the method of the invention.
amplification for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples. The methods, kits and oligonuclectides are useful for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples e.g. for disease diagnosis and gene analysis. The present sequence is oligo dT PCR primer used to illustrate the method of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Sequential consensus region-directed amplification for sorting mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples, useful for disease diagnosis and gene analysis -

The present invention describes nucleic acid molecules which modulate the synthesis, expression and/or stability of a mRNA encoding 1 or more receptors of vascular endothelial growth factor (VEGF). A patient (preferably human) having a condition associated with the level of the fms-like tyrosine kinase 1 (flt-1), kinase insert domain containing receptor (KDR) and/or foetal liver kinase 1 (flk-1) (e.g. tumour angiogenesis, ocular diseases, psoriasis and rheumatoid arthritis) can be treated by administering the nucleic acid molecule or the expression vector to the patient. AAX67275 to AAX75752 represent specific examples of nucleic acid molecules from the present invention.
                                                                                                                        vascular endothelial growth factor receptor; VBGF receptor; flt-1; flk-1; KDR; hammerhead ribozyme; hairpin ribozyme; cleavage; tumour angiogenesis; psoriasis; rheumatoid arthritis; ocular disease; fms-like tyrosine kinase 1; kinase insert domain containing receptor; foetal liver kinase 1; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        or

The present invention describes nucleic acid molecules which modulate the synthesis, expression and/or stability of a mRNA encoding 1 or more receptors of vascular endothelial growth factor (VEGF). A patient (preferably human) having a condition associated with the level of the fms-like tyrosine kinase 1 (flt-1), kinase insert domain containing receptor (KDR) and/or foetal liver kinase 1 (flk-1) (e.g. tumour anglogenesis, ocular diseases, psoriasis and rheumatoid arthritis) can be treated by administering the nucleic acid molecule or the expression vector to the patient. AAX67275 to AAX7575 represent specific examples of nucleic acid molecules from the present invention.
flk-1; KDR; hammerhead ribozyme; hairpin ribozyme; cleavage;
tumour anglogenesis; psoriasis; rheumatoid arthritis; ocular disease;
fms-like tyrosine kinase 1; kinase insert domain containing receptor;
foetal liver kinase 1; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                          Nucleic acid molecule modulating VEGF receptor(s) gene expression or mRNA stability - useful for treating e.g. tumour angiogenesis, psoriasis, rheumatoid arthritis, etc., in a human patient
                                                                                                                                                                                                                                                                                                                                                                  Escobedo J, McSwiggen J, Pavco P,

New nucleic acids that interact, and optionally cleave, target sequences, used to treat cancer

Claim 77; Page 79; 148pp; English.

Tink, having endonuclease activity. (A), and more generally any catalytic nucleic acid (A') that modulates expression of the ocetrogen receptor gene, are used to treat cancer (particularly of breast or endometrium), in vivo or by transforming cells ex vivo and implanting treated cells, or for other conditions associated with levels of constrogen receptor. Because of the high selectivity for targeted RNA, (A) can also be used to correlate inhibition of gene expression with also be used to correlate inhibition of gene expression with also be used to correlate inhibition of gene expression with targets, and as research reagents (for RNA, in the same way that restriction endonucleases are used with DNA). The combination of modifications in (A) improves resistance to nucleases, binding affinity and/or activity. AAA23503 to AAA24748 to AAA25992 represent their corresponding target sequences, AAA25939 to AAA25992 represent their corresponding target sequences. AAA25930 to AAA36219 represent cestrogen receptor hairpin ribozyme sequences. AAA26219 to AAA36211 represent their corresponding target sequences. AAA26219 to AAA36211 represent certrogen receptor hairpin ribozyme sequences. AAA26219 to AAA36211 represent certrogen receptor hairpin ribozyme sequences. AAA26219 to AAA36211 represent certrogen receptor hairpin ribozyme sequences. AAA26219 to AAA36211 represent certrogen receptor hairpin ribozyme sequences. AAA26219 to AAA36211 represent certrogen receptor hairpin ribozyme sequences. AAA26219 to AAA36211 represent certrogen receptor hairpin ribozyme sequences and manisense oligonucleotides used in the The present invention describes nucleic acids (A) that interact stably with a target sequence and contain at least one phosphoro(di)thioate exemplification of the present invention.

The specification describes a method for determining a nucleotide sequence signature. The method comprises obtaining optical measurements with values indicating each nucleotide in a group of nucleotide positions, adjusting the values until the ratio of highest value in the set to next highest values in the set is at least a predetermined factor, and generating a base call for a position in the group based on results after the adjustment of values. The method is used for determining a signature of a nucleotide sequence, and for determining
Determining nucleotide sequence signature, by obtaining optical values for each nucleotide position in a group, adjusting them to get ratio of final highest values near predetermined factor, generating base call
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     a nucleotide sequence of a polynucleotide from a series of optical measurements. The present sequence represents an adaptor, which is used in the course of the invention.

Collection of binding groups for determining or typing samples, especially clinical samples, has groups capable to identify essentially all members of the family of nucleic acids of relatively high significance

Disclosure; Page 12; 166pp; English.

The present invention describes a collection of binding groups for a family of nucleic acids comprising members of relative high and relative

low significance, where the binding groups are selected to be capable to identify, alone or in combination, essentially all members of the family of nucleic acids of relatively high significance. The collection of binding groups is useful for typing of nucleic acid in a clinical sample, by contacting the nucleic acid with the collection and determining whether one or more binding groups bound to the nucleic acid of the sample. This method is useful for determining whether the sample comprises at least a part of a member of relatively high significance of a family of nucleic acids. The collection of binding groups is useful for aliannosing the severity of a disease caused by a pathogen containing a member of a family of nucleic acids. ABL88779 to ABL89321 represent oligonucleotide sequences used in the exemplification of the present invention.

The sequences, when introduced into a cell either predisposed to undergo cell death or in the process of undergoing cell death, prevent, delay or rescue the cell from death, hence, these sequences are named "protective sequences". The sequences are useful for treating and/or ameliorating cancer, autoimmune diseases and neurological disorders e.g. stroke. Further examples of diseases which may be treated by the present

                                                                                                                                                                                                                                                                                                                                                                                                                                                           The invention relates to a novel isolated molecule comprising bases 2-8 or 13-16 of 2 16 base pair sequences, or comprising a 1731 base pair sequence, all given in the specification or at least 95 % identity with the 1731 bp sequence. The moleic acid molecule is useful in regulating apoptosis in cells and in drug screening. The method is useful in that can intering the induction of apoptosis in cells, in identifying an agent that can facilitate the induction of apoptosis in cells, and in inhibiting the growth of a cancer. This polymuleotide sequence represents a ribozyme substrate target sequence relating to the

The ALL-1 gene rearrangement was studied in 3 adult patients with acute myeloid leukaemia and who lacked cytogenetic evidence of 11g23 translocations. Oligonucleotide primers 3.1c and 5.3 (see AAQ75191 and AAQ75192) were used in a first PCR amplification, followed by nested PCR using the primers 6.1 and 3.2c (AAQ75193 and AAQ75194). A single rearranged ALL-1 band was seen for each patient. Each clone begins and ends with a portion of ALL-1 axon 5, the 5'-3' order of ALL-1 exons within each clone was 5-6-2-3-4-5. This novel exon structure indicates that the ALL-1 rearrangement in each patient is the result of direct tandem duplication of a portion of New acute lymphocytic leukaemia gene prods. - used for the diagnosis and treatment of leukaemias, partic, acute lymphoblastic or nonlymphoblastic leukaemia (Updated on 25-MAR-2003 to correct PN field.) Example 6; Page 58; 207pp; English.

Detection of ALL-1 gene rearrangement or mutation in solid tumour using ALL-1-specific probe or primer

Example 1; Column 13; 10pp; English

AAT48513-T48518 are PCR primers used for the isolation of the ALL-1 gene from total cDNA from the human gastric carcinoma cell line Mgc80-3 and subsequent subcloning of the gene into the TA vector analysed for ALL-1 gene rearrangements. ALL-1 gene rearrangement results in a variety of solid tumours and is also responsible for acute lymphoblastic leukaemia (ALL) and cutte myeloid leukaemia (ALL). The ALL-1 gene is located at chromosome 11 band q23, in leukaemia (ALL). The ALL-1 gene is located at chromosome 11 band q23, in leukaemia (ALL) with translocations involving 11q23, the ALL-1 gene fuses with one of many different genes, or (in the case of AML) self fusion resulting in a partially duplicated gene and a transcript with an in-frame fusion of either exon 6 or exon 8 with exon 2. The primers (which enternances of human solid tumony and loukaemise as mantianed. prognosis of human solid tumours and leukaemias, as mentioned

```
A method for DNA analysis based on a complementary extension reaction using a DNA polymerase, comprises a combination of fragment walking and DNA sequencing. DNA fragments are formed by digestion of DNA with a restriction enzyme and the targeted DNA sequence can be determined directly from the digested DNA fragments. By exploring the overlapping sequence of the determined base sequence, the overall base sequence of a lengthy DNA can be determined with low redundancy without cloning subcloning. In addition, the method can be done with commercially existing methods. AAT73291-92 are primers than required in existing methods. Primer extension was carried out using 16 primers

Set of 11 oligo-nucleotide probes for identification of flaviviruses - comprising probes specific for tick, Japanese, Murray Valley and St. Louis encephalitis, yellow fever, dengue, and West nile

Claim 1; Columns 7-8; 4pp; Russian.

The present sequence, a probe for the identification of dengue I fever virus, is a member of a probe set for the detection of flaviviruses. The probe set gives increased accuracy in identification of flaviviruses because of the use of highly specific probes.
Use of the probe set for the identification of flaviviruses involved the synthesis of deoxyoligonucleotides, study of their specificity, immobilisation of RNA on nitrocellulose filters, labelling with 32P and hybridisation. After hybridisation the radioactivity was measured with a scintillation counter, and signals 2 to 3 fold higher than the background considered positive. The probe set was used to test 50 strains of 16 types of flavivirus.

AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae (see AAX91990). C. pneumoniae causes respiratory disease such as pneumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent by the open reading frames of the C. pneumoniae genome (see AAY34584-AAY35879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae nuclectides sequences can also be used as immunogenic compositions, especially where the vector directs the expression of a neutralising epitope of C. pneumoniae.
                                                                                                                                                                                                                                                                           Respiratory disease; pneumonia; bronchitis; heart disease; sarcoidosis; sinusitis; purulent otitis media; erythema nodosum; pharyngitis; vaccine; neutralising epitope; PCR primer; ss.
                                                                                                                                                                                                                   PCR primer used to amplify an ORF of Chlamydia pneumoniae.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Sequence 20 BP; 9 A; 4 C; 6 G; 1 T; 0 other;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Genome sequence of Chlamydia pneumoniae
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Page 1847; Disclosure; 1912pp; English.

Isolated, synthetic or recombinant chi-conotoxin peptide capable of inhibiting neuronal amine transporter used for treatment or prophylaxis of urinary or cardiovascular conditions, mood disorders, or treatment/control of pain/inflammation

Example 7; Page 30; 47pp; English.

Primer CHI-1B was designed from the mature chi-MrIA peptide sequence
(AAY92229), a novel conotoxin. CHI-1B was used with API (AAA09109) to
amplify the 5. region of the chi-MrIA gene from Conus marmoreus. The
camplify the 5. region of the chi-MrIA gene from Conus marmoreus. The
peptide is an inhibitor of the neuronal amine transporters, especially
the neuronal noradrenaline transporter. Inhibitors of noradrenaline
re-uptake which have a negligible anti-cholinergic effect are
particularly useful in the treatment of lower urinary tract disorders.
Chi-MrIA (0.1 nM-1 micro M) inhibited the accumulation of radiolabeled
noradrenaline in a concentration-dependent manner, with a log IC-50
(Allue of -8.17 plus or minus 0.0275 (n = 4). The concentration of
chi-MrIA required to inhibit the accumulation by 50 percent was found to
be approximately 7 nM. This concentration is approximately one order of
magnitude lower than that needed for desipramine to produce the same
effect. The peptides are useful for the treatment or prophylaxis of
urinary or cardiovascular conditions or diseases (arrhythmia or coronary
che treatment or control of pain or inflammation (chronic pain,
neuronarhic nain or inflammation (chronic pain, neuropathic pain or inflammatory pain).

```
New antisense compounds capable of modulating expression of human protein phosphatase 1B, useful for diagnosis, prophylaxis and treatment of diseases associated with expression of protein phosphatase
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  The invention is directed to antisense compounds, particularly oligonucleotides which are targetted to a DNA encoding protein compounds ase 18 (PTPLB) to modulate its expression. The antisense diseases associated with the expression of PTPLB, to prevent of delay infection, inflammation and tumour formation and as a research reagent. The PTPLB DNA is useful in gene therapy. The present sequence is an antisense oligonucleotide with a phosphorothicate backbone. This oligo is targetted to human PTPLB to inhibit its expression.

```
The present invention relates to a method for stimulating an immune response. The method comprises administering an immunostimulatory nucleic acid to a non-rodent subject in sufficient quantity to stimulate an nucleic acid. The present sequence is one such immunostimulatory (py-rich) one thymidine (T) rich. The method is used to vaccinate subjects and/or orthomyxoviridae, viral antigens (e.g. harpesviridae, retroviridae adding tumour antigens, viral antigens (e.g. harpesviridae, retroviridae haemphilus, campylobacter, clostridium, Escherichia coli and/or also useful for preventing cancer, asthma, infectious disease, allergy or immune deficiency. The present sequence can also be used to redirect a more to a the immune cells.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          the present sequence may have a phosphorothioate backbone.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        1.3%; Score 14; DB 1; Length 20; 100.0%; Pred. ```

The invention relates to inhibiting angiogenesis in a subject, comprising administering at least one antiangiogenic nucleic acid molecule.

Also included is a kit comprising a first container housing the artiangiogenic nucleic acids, and instructions for administering them to a subject having a condition characterised by unwanted angiogenesis.

The method is useful for inhibiting angiogenesis associated with solid tumour growth, tumour metaetasis, precancerous lesion, rheumatoid arthritis, psoriasis, diabetic retinopathy, retinopathy of prematurity, macular degeneration, corneal graft rejection, neovascular glaucoma, retrolental fibroplasia, rubeosis, Osler-Webber Syndrome, myocardial angiogenesis, plaque neovascularisation, telangicatedia, haemophiliac joints, angiogibroma, wound granulation, intestinal adhesions, atherosclerosis, scleroderma and hypertrophic scars. The present sequence is an antiangiogenic nucleic acid of the invention.

Butler MM, Mckay R;

Monia BP,

The invention relates to a compound targeted to a nucleic acid molecule encoding protein phosphatase 1B (PTP1B), which specifically hybridises with and inhibits the expression of PTP1B. The compounds of the invention are useful for inhibiting the expression of PTP1B in liver, kidney or adipose cells or tissues and for treating an animal, preferably human, having a disease or condition associated with PTP1B, including metabolic diseases or conditions, e.g. type 2 diabetes and obseity, or useful for decreasing blood (serum or plasma) glucose levels in an animal a disease or condition associated with PTP1B, and for preventing or disease or condition associated with PTP1B, and for preventing or delaying the onset of delaying the onset of a disease or condition associated with PTP1B, and for preventing or represents a PTP1B mRNA level inhibition antisense oligonucleotide of the

Designing capture oligonucleotide probes for use on a support to which complementary oligonucleotides hybridize with little mismatch -

Example 5; Fig 29; 300pp; English,

XUX#X#X#X#X#X##X##X8X88888

The present invention describes a method (MI) for designing capture coligonucleotide probes (I) for use on a support to which complementary oligonucleotide probes (II) will hybridise with little mismatch, where cligonucleotide probes (II) will hybridise with little mismatch, where cligonucleotide probes (II) will hybridise with little mismatch, where for detecting infectious diseases caused by bacterial infectious agents of samonellar, Listeria monocytogenes and Haemophilus influenza, fungal infectious agents or confermans. Candida albicans and Aspergillus funigautus, viruses e.g. T-cell lymphocytotrophis cirus, selected from Onchoverva volvulus, Entamoeba histolyfica and Dracunculus confinesis. The method is also useful for detecting genetic diseases such confines in method is also useful for detecting genetic diseases such confined in DNA amplification, replication, recombination or repair, the concert is specifically associated with a gene selected from BRCA1 gene, fuvour papillomavirus types 16 and 18 and liver cancers. The method is also used for environmental monitoring, forensics and the food electron microscope and infrared microscope) the support at the categorical and orrelating a comprises scanning (using e.g. a scanning particular sites and identifying if ligation of the oligonucleotide probe control and correlating (using a conjuguer) identified ligation to a presence or absence of the target nucleotide sequences. AB182074 to of the present invention.

The present invention relates to methods for treating or preventing cancer, involving administering to a subject having or at risk of cancer, involving administering to a subject having or at risk of developing cancer immunostimulatory nucleic acids that induce expression of cell surface antigens and antibodies. The methods are useful for treating or preventing cancer such as basal cell carcinoma, bladder cancer, bone cancer, brain and central nervous system (CNS) cancer, breast cancer, cervical cancer, colon and rectum cancer, connective tissue cancer, oseophageal cancer, eye cancer, Hodgin's lymphoma, relations, inver cancer, lange, mysloma, oral cavity cancer, ovarian cancer, pancreatic cancer, prostate cancer, rhabdomyosarcoma, skin cancer, stomach cancer, prostate cancer, rhabdomyosarcoma, skin cancer, stomach cancer, testicular cancer, and uterine cancer. The present sequence is an immunostimulatory oligonucleotide described in the exemplification of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Treating or preventing cancer, such as basal cell carcinoma, comprises administering immunostimulatory nucleic acids that induce expression of cell surface antigens and antibodies to a subject having or at risk of

Method for detection of point mutation(s) in nucleic acid segments - where segments encode GTP binding protein or sub-unit and method involves amplification followed by sequence-specific probe hybridisation

Example; Page 57; 69pp; English.

This probe corresponds to the sequence around codon 61 of the ras p21 gene. It is one of 63 probes which are of use in detecting point mutations in nucleic acid sequences encoding ras proteins, specifically at positions 12, 13 and 61, three potentially oncogenic sites. See AAQ13900-Q13962.

Sandwich hybridisation of single strand nucleic acid - using short immobilised capture probe and detection probe with non-radioactive label, for diagnosing e.g. human papilloma virus or HIV

Claim 42; Page 39; 51pp; French.

Target DNA corresponding to HIV-1 gag region is detected using a capture probe (AAQ20634) fixed passively to a solid hydrophobic support together with this detection probe labelled with a non-radioactive marker. The capture and detection probes are able to hybridise to non-overlapping segments of the target sequence. See AAQ20389-Q20420 and AAQ20630.

The present invention describes nucleic acid molecules which modulate the synthesis, expression and/or stability of a mRNA encoding 1 or more receptors of vascular endothelial growth factor (VEGF). A patient (preferably human) having a condition associated with the level of the fms-like tyrosine kinase 1 (flt-1), kinase insert domain containing arceptor (KDR) and/or foetal liver kinase 1 (flk-1) (e.g. tumour angiogenesis, ocular diseases, psoriasis and rheumatoid arthritis) can be treated by administering the nucleic acid molecule or the expression vector to the patient. AAX67275 to AAX75752 represent specific examples of nucleic acid molecules from the present invention.
